Energy inequalities for cutoff functions and some applications

Sebastian Andres[*], Martin T. Barlow[†]

Abstract

Let $(\mathcal{X}, d, m)$ be a metric measure space with a local regular Dirichlet form. We establish necessary and sufficient conditions for upper heat kernel bounds with sub-diffusive space-time exponent to hold. This characterization is stable under rough isometries, that is it is preserved under bounded perturbations of the Dirichlet form. Further, we give a criterion for stochastic completeness in terms of a Sobolev inequality for cutoff functions. As an example we show that this criterion applies to an anomalous diffusion on a geodesically incomplete fractal space, where the well-established criterion in terms of volume growth fails.

Keywords: Heat kernels, Sobolev inequality, Faber-Krahn inequality, rough isometry, stochastic completeness, conservativeness, Sierpinski carpet, anomalous diffusion

Subject Classification. Primary: 60J35; Secondary: 60J25, 31C05, 31C25

1 Introduction

Let $(\mathcal{X}, d)$ be a locally compact metric space and let m be a positive Radon measure on $\mathcal{X}$ with $\operatorname{supp}[m] = \mathcal{X}$. We will refer to such a triple $(\mathcal{X}, d, m)$ as a *metric measure space*, and denote by $\langle ., . \rangle$ the inner product in $L^2(\mathcal{X}, m)$. We consider a regular, strongly local Dirichlet form $(\mathcal{E}, \mathcal{F})$ on $L^2(\mathcal{X}, m)$ (see [FOT]). Let $\mathcal{L}$ be the (negative definite) generator of $\mathcal{E}$; this is a self-adjoint operator in $L^2(\mathcal{X}, m)$ such that

$$\mathcal{E}(f, g) = -\langle \mathcal{L} f, g \rangle \quad \text{for all } f \in \mathcal{D}(\mathcal{L}),\ g \in \mathcal{F},$$

and let $\{P_t\}_{t \geq 0}$ be the associated semigroup. If P_t has a density $p_t(x, y)$ with respect to m then after some regularization we call this the *heat kernel* on the *metric measure Dirichlet space* (or *MMD space*) $(\mathcal{X}, d, m, \mathcal{E})$. Our main interest is in upper bounds on $p_t(x, y)$. Write $B(x, r)$ for balls in $(\mathcal{X}, d)$ and set

$$V(x, r) = m(B(x, r)). \tag{1.1}$$

---

Most familiar are Gaussian upper bounds of the form

$$p_t(x,y) \le \frac{c_1}{V(x,t^{1/2})} \exp\Big(- c_2 \frac{d(x,y)^2}{t} \Big); \tag{1.2}$$

these arise (with lower bounds of the same form but with different constants) in the case of uniformly elliptic divergence form PDE, and manifolds with Ricci curvature bounded uniformly below – see [Ar, LY].

If (1.2) holds we will say $(\mathcal{X},\mathcal{E})$ satisfies the condition UHK(2); if in addition Gaussian lower bounds hold we say HK(2) holds. One can ask for characterizations of these bounds, and in particular for characterizations which are *stable*, that is that are preserved under bounded perturbation of the Dirichlet form. More precisely, a property (P) of $(\mathcal{X},\mathcal{E})$ is stable if when $(\mathcal{E}_i,\mathcal{F})$ are two Dirichlet forms on $L^2(\mathcal{X},m)$ with

$$C^{-1}\mathcal{E}_1(f,f) \le \mathcal{E}_2(f,f) \le C\mathcal{E}_1(f,f), \quad f\in\mathcal{F},$$

then (P) holds for $(\mathcal{X},\mathcal{E}_1)$ if and only if it holds for $(\mathcal{X},\mathcal{E}_2)$. In the manifold case stability for HK(2) was proved in [Gr0, SC1] by showing that these Gaussian bounds are equivalent to *volume doubling* (denoted VD) plus a family of Poincaré inequalities – see below for the precise definitions. If VD holds then stability for UHK(2) is a consequence of the results of [Gr3], where it is shown that UHK(2) is equivalent to a Faber Krahn inequality FK(2), which controls the smallest eigenvalue of domains in $\mathcal{X}$.

The Gaussian bounds (1.2) arise due to the standard space-time scaling relation $t=r^2$. More general possibilities can arise; for various exact fractals (see [Ba1]) one can have $V(x,r)\asymp r^\alpha$ and a space time scaling of $t=r^\beta$, where $\alpha\in[1,\infty)$ and $\beta\in[2,1+\alpha]$; the case when $\beta\neq 2$ is called *anomalous diffusion.* Since we wish to be able to consider spaces with different local and global structure, we introduce a more general space-time scaling function Ψ. Let $\beta_L\ge 2$, $\beta\ge 2$, and set

$$\Psi(r)=\Psi_{\beta_L,\beta}(r)=\begin{cases} r^{\beta_L} & \text{if } 0\le r\le 1,\\ r^{\beta} & \text{if } r>1.\end{cases} \tag{1.3}$$

We will write UHK(Ψ) for the heat kernel upper bounds associated with Ψ – see Definition 1.6 below for their precise form. Our main theorem is a stable characterization of UHK(Ψ), in terms of Faber-Krahn inequality FK(Ψ), and a new condition denoted CSA(Ψ), which controls the energy of cutoff functions in annuli.

To state our results precisely, we need a number of further definitions.

Since $\mathcal{E}$ is regular, each function $f\in\mathcal{F}$ admits a quasi-continuous version $\tilde f$ (see Theorem 2.1.3 in [FOT]). Throughout the paper, we will abuse notation and take the quasi-continuous version of f without writing $\tilde f$. Another consequence of regularity is that $\mathcal{E}(f,g)$ can be written in terms of a signed measure $\Gamma(f,g)$ as

$$\mathcal{E}(f,g)=\int_{\mathcal{X}} d\Gamma(f,g).$$

For any essentially bounded $f \in \mathcal{F}$, $\Gamma(f,f)$ is the unique Borel measure on $\mathcal{X}$ (called the energy measure) on $\mathcal{X}$ satisfying

$$\int_{\mathcal{X}} g\, d\Gamma(f,f) = 2\mathcal{E}(f,fg) - \mathcal{E}(f^2,g)$$

for all essentially bounded $g \in \mathcal{F}$; $\Gamma(f,g)$ is then defined by polarization.

Example. (Davies [D]). Let (M,d) be a manifold with Riemannian volume measure μ, and $\mathcal{E}(f,f) = \int |\nabla f|^2 d\mu$. Let $\sigma > 0$, and $dm = \sigma^2\, d\mu$. Then

$$\mathcal{L}f = \sigma^{-2}\nabla(\sigma^2\nabla f),$$

and $d\Gamma(f,f) = |\nabla f|^2\sigma^2 d\mu$.

For later use we collect from [FOT, Section 3.2] some properties of the energy measure.

i) **Locality.** For all functions $f, g \in \mathcal{F}$ and all measurable sets $G \subset \mathcal{X}$ on which f is constant

$$\mathbb{1}_G\, d\Gamma(f,g) = 0.$$

ii) **Leibniz and chain rules.** For $f, g \in \mathcal{F}$ essentially bounded and $\varphi \in C^1(\mathbb{R})$,

$$\begin{aligned} d\Gamma(fg,h) &= f\, d\Gamma(g,h) + g\, d\Gamma(f,h), \\ d\Gamma(\varphi(f),g) &= \varphi'(f)\, d\Gamma(f,g). \end{aligned}$$

We note also the following result of Le Jan [LJ, Proposition 1.5.5(b)] – see also [Mos], p. 389 for a simple proof.

Lemma 1.1. *Let $\mathcal{X}$ be a MMD space. Suppose that $(\mathcal{E}_i, \mathcal{F}), i = 1,2,$ are strongly local regular Dirichlet forms that satisfy*

$$C^{-1}\mathcal{E}_1(f,f) \le \mathcal{E}_2(f,f) \le C\mathcal{E}_1(f,f), \quad f \in \mathcal{F}. \tag{1.4}$$

Then their energy measures $\Gamma^{(i)}$ satisfy

$$C^{-1}d\Gamma^{(1)}(f,f) \le d\Gamma^{(2)}(f,f) \le C d\Gamma^{(1)}(f,f), \text{ for all } f \in \mathcal{F}. \tag{1.5}$$

We now introduce a number of conditions which the space $\mathcal{X}$ and Dirichlet form $\mathcal{E}$ may or may not satisfy.

Definition 1.2. We say that $(\mathcal{X}, d, m)$ satisfies *volume doubling* (VD) if there exists a constant C_D such that for every $x \in \mathcal{X}$, $r > 0$,

$$V(x,2r) \le C_D V(x,r). \tag{1.6}$$

We next introduce the Faber-Krahn inequality: see [GT], Section 3.3 for more details. For any open set $D \subset \mathcal{X}$, $\mathcal{F}_D$ is defined to be the closure in $\mathcal{F}$ of the set of all functions in $\mathcal{F}$ that are compactly supported in D. For $D \subset \mathcal{X}$ we write $\lambda_1(D)$ for the smallest (Dirichlet) eigenvalue of $\mathcal{L}$ on D; this can be defined by the variational formula

$$\lambda_1(D) = \inf\Big\{\frac{\mathcal{E}(f,f)}{||f||_2^2} : f \in \mathcal{F}_D, f \ne 0\Big\}. \tag{1.7}$$

Definition 1.3. The MMD space $(\mathcal{X}, \mathcal{E})$ satisfies the *Faber-Krahn inequality* FK(Ψ) if there exists a constant C_F and $\nu > 0$ such that for any ball $B = B(x,r)$ and open set $D \subset B$,

$$\lambda_1(D) \geq \frac{C_F}{\Psi(r)} (m(B)/m(D))^{\nu}. \tag{1.8}$$

We remark that the value of ν turns out to be unimportant.

Definition 1.4. We say that the *Poincaré inequality* PI(Ψ) holds if there exists a constant C_P such that for all balls $B = B(x,r)$ and $f \in \mathcal{F}$,

$$\inf_{a \in \mathbb{R}} \int_B (f-a)^2 dm = \int_B (f - \overline{f}_B)^2 dm \leq C_P \Psi(r) \int_B d\Gamma(f,f).$$

Here $\overline{f}_B$ is the mean of f on B.

Associated with the Dirichlet form $(\mathcal{E}, \mathcal{F})$ and semigroup (P_t) is a Hunt process $X = (X_t, t \geq 0, \mathbb{P}^x, x \in \mathcal{X} - \mathcal{N})$. Here $\mathcal{N}$ is 'properly exceptional': $m(\mathcal{N}) = 0$ and $\mathbb{P}^x(X_t \in \mathcal{N}$ for some $t > 0) = 0$ for all $x \in \mathcal{X} - \mathcal{N}$ – see [FOT, p. 134]. This Hunt process is unique up to a properly exceptional set – see [FOT, Theorem 4.2.7]. We fix X and $\mathcal{N}$, and write

$$\mathcal{X}_0 = \mathcal{X} - \mathcal{N}. \tag{1.9}$$

While the semigroup (P_t) associated with $\mathcal{E}$ is defined on L^2, a more precise version, with better regularity properties, can be obtained if we set, for bounded Borel f,

$$P_t f(x) = \mathbb{E}^x f(X_t), \quad x \in \mathcal{X}_0.$$

The heat kernel associated with (P_t) (if it exists) is a measurable function $p_t(x,y) : (0,\infty) \times \mathcal{X}_0 \times \mathcal{X}_0 \to (0,\infty)$ such that

$$\mathbb{E}^x f(X_t) = P_t f(x) = \int p_t(x,y) f(y)\, m(dy),\ x \in \mathcal{X}_0, f \in L^\infty(\mathcal{X}), \tag{1.10}$$

$$p_t(x,y) = p_t(y,x), \ \text{ for all } t > 0,\ x,y \in \mathcal{X}_0, \tag{1.11}$$

$$p_{s+t}(x,z) = \int p_s(x,y) p_t(y,z)\, m(dy),\ \text{ for all } s > 0, t > 0,\ x,z \in \mathcal{X}_0. \tag{1.12}$$

While (1.10) only defines $p_t(x,\cdot)$ m-a.e., using the Chapman-Kolmogorov equation (1.12) one can regularise $p_t(x,y)$ so that (1.10)–(1.12) hold on all of $\mathcal{X}_0$. For more details see [GT].

Define the function

$$\Phi(R,t) = \sup_{s>0} \Big(\frac{R}{s} - \frac{t}{\Psi(s)} \Big). \tag{1.13}$$

The following lemma summarises some properties of this function – see Section 3.3 of [GT] and in particular Example 3.18.

Lemma 1.5. *$\Phi(R,t)$ is non-negative, increasing in R and decreasing in t. We have*

$$\Phi(R,t) \asymp \begin{cases} \left(\frac{R^{\beta_L}}{t}\right)^{1/(\beta_L-1)}, & \text{if } t \le R, \\ \left(\frac{R^{\beta}}{t}\right)^{1/(\beta-1)}, & \text{if } t \ge R. \end{cases} \tag{1.14}$$

Further $\Phi(R,\Psi(R)) \le \beta_2^{-1/(\beta_2-1)}$, where $\beta_2 = \beta_L \vee \beta$.

We define Ψ^{-1} to be the inverse of Ψ, so that

$$\Psi^{-1}(s) = s^{1/\beta_L} 1_{(s\le 1)} + s^{1/\beta} 1_{(s>1)}.$$

Definition 1.6. We say (p_t) satisfies UHK(Ψ) if there exists a properly exceptional set $\mathcal{N}_0$ and constants c_1, c_2 such that

$$p_t(x,y) \le V(x,\Psi^{-1}(c_1 t))^{-1} \exp(-\Phi(c_2 d(x,y),t)) \tag{1.15}$$

for all $t > 0$ and for all $x,y \in \mathcal{X} - \mathcal{N}_0$. If a similar lower bound (with different constants c_i) also holds then we say that HK(Ψ) holds.

When $\Psi(r) = r^\beta$ we will write PI(β) etc. for the condition PI(Ψ).

As explained above, we wish to find a stable characterization of the heat kernel bounds UHK(Ψ). In view of Lemma 1.1, the characterizations of HK(2) and UHK(2) in terms of Faber-Krahn and Poincaré inequalities are stable. It is easy to see that the natural generalization of these to more general Ψ fails. Let $\Psi_2 \ge \Psi_1$ with $\Psi_2(r)/\Psi_1(r) \to \infty$, and let $\mathcal{X}$ be an unbounded space satisfying HK(Ψ_1). Then $\mathcal{X}$ also satisfies FK(Ψ_1) and PI(Ψ_1), and so by the monotonicity of these conditions in Ψ, it is immediate that $\mathcal{X}$ satisfies FK(Ψ_2) and PI(Ψ_2). However, it is straightforward to check that HK(Ψ_1) and UHK(Ψ_2) cannot both hold. At a more fundamental level, the conditions PI(Ψ) and FK(Ψ) ensure that the heat equation homogenises over a ball of radius R in time at most $\Psi(R)$, but do not exclude the possibility that this might occur more quickly. To 'capture' HK(Ψ) one needs a condition which gives an upper bound on the rate at which heat, or the diffusion X, can move on the space $\mathcal{X}$. Such a condition was found in [BB3, BBK], which gave a stable characterization of HK(Ψ).

Definition 1.7. Let $U \subset V$ be open sets in $\mathcal{X}$ with $U \subset \overline{U} \subset V$. We say a continuous function φ is a *cutoff function for $U \subset V$* if $\varphi = 1$ on U and $\varphi = 0$ on V^c.

Definition 1.8 (Condition (CS(Ψ)). (See [BB3, BBK].) We say that condition CS(Ψ) holds if there exist constants c_1 and $\theta \in (0,1]$ such that the following holds. For every ball $B(x_0,r)$ there exists a cutoff function φ with $\varphi = 1$ on $B(x_0,r/2)$ and $\varphi = 0$ on $B(x_0,r)^c$, with the following properties.
(1) φ is Hölder continuous of order θ.
(2) If $0 < s \le r$ and $f \in \mathcal{F}$ then

$$\int_{B(y,s)} f^2 \, d\Gamma(\varphi,\varphi) \le c_1 (s/r)^{2\theta} \Big(\int_{B(y,2s)} d\Gamma(f,f) + \Psi(s)^{-1} \int_{B(y,2s)} f^2 dm \Big). \tag{1.16}$$

'CS' here refers to 'cutoff Sobolev'; this condition ensures the existence of a large class of cutoff functions with low energy. The main theorem of [BB3, BBK] is that HK(Ψ) is equivalent to VD +PI(Ψ) + CS(Ψ). While the condition CS(Ψ) is hard to verify, it is stable. Further, this stability allows estimates on (for example) the heat kernel on the Sierpinski carpet to be transferred to manifolds, graphs, or domains in $\mathbb{R}^d$ which are roughly isometric to the Sierpinski carpet. For rough isometries see [Kan], and a for more detailed discussion of this point see [BBK, Section 5].

We now introduce a simplication of the condition CS(Ψ), which controls the energy of cutoff functions in annuli.

Definition 1.9. Let D_0, D_1 be open subsets of $\mathcal{X}$ with $D_0 \subset \overline{D}_0 \subset D_1$, and let $U = D_1 - \overline{D}_0$. We say that condition CSD(D_0, D_1, θ) holds if there exists a cutoff function φ for $D_0 \subset D_1$ such that if $f \in \mathcal{F}$ then,

$$\int_U f^2 \, d\Gamma(\varphi, \varphi) \leq \frac{1}{8} \int_U \varphi^2 d\Gamma(f, f) + \theta \int_U f^2 dm. \tag{1.17}$$

Definition 1.10 (Condition (CSA(Ψ)**).** We say that condition CSA(Ψ) holds if there exists a constant C_S such that for every $x \in \mathcal{X}$, $R > 0$, $r > 0$ the condition CSD($B(x,R), B(x,R+r), C_S\Psi(r)^{-1}$) holds.

Remark 1.11. 1. If VD holds then CS(Ψ) implies CSA(Ψ) – see Lemma 5.7.
2. Note that CSA(Ψ) does not require the Hölder continuity of the cutoff function.
3. It is essential for the use of (1.17) in Lemma 3.3 that the constant in front of the first term on the right hand side is less than $\frac{1}{4}$. However, as we will see in Section 5, the inequality CSA(Ψ) has a 'self-improving' property, which enables one to alter the weights of the two terms on the right-hand side.
4. It is easy to see by using linear cutoff functions that CSA(2) holds on any manifold.
5. The bound (1.17) is not symmetric between φ and $1 - \varphi$, but very often we will just use the fact that $\varphi \leq 1$ in the first term on the right hand side.
6. In view of Lemma 1.1 and the results of Section 5, the condition CSA(Ψ) is stable – see Corollary 5.2.
7. See [Bas] for the use of an inequality similar to CS(Ψ) to prove stability of the elliptic Harnack inequality for a class of graphs.

Our first main theorem is the following characterization of UHK(Ψ).

Theorem 1.12. *Assume that $\mathcal{X}$ satisfies VD and is unbounded in the metric d. The following are equivalent:*
(1) FK(Ψ) *and* CSA(Ψ).
(2) UHK(Ψ).

Remark 1.13. (1) See [GH] for several other conditions equivalent to UHK(β). Note however that unlike (1) above, none of these were known to be stable under bounded perturbation of the Dirichlet form $\mathcal{E}$.

(2) The reader may wonder if while CSA(Ψ) is sufficient for upper bounds, one needs the stronger CS(Ψ) to obtain lower bounds as well. However, we expect that HK(Ψ) is equivalent to VD + PI(Ψ) + CSA(Ψ). In fact, VD + PI(Ψ) is enough to give FK(Ψ), so using Theorem 1.12 one obtains UHK(Ψ). Given this, the methods of Stroock and Saloff-Coste [SCS], and Fabes-Stroock [FS] should then lead to a matching lower bound.

The main theorem of [BB3, BBK] was proved using Moser's method [Mo1]. To prove the implication (1) $\Rightarrow$ (2) in Theorem 1.12 we first show in Proposition 2.3 that CSA(Ψ) gives a generalization of the 'Davies-Gaffney' bound of [D]. Next, we use techniques developed in [Gr0, CG] to prove a mean value inequality for caloric functions (i.e. solutions of the heat equation), which leads to the pointwise bounds UHK(Ψ). For the easier implication (2) $\Rightarrow$ (1) we use the method of [BBK], but since CSA(Ψ) is rather simpler than CS(Ψ) the proof is much quicker.

Our second main result concerns stochastic completeness.

Definition 1.14. The process associated X is called *stochastically complete* if $P_t 1 = 1$ m-a.e. for some (or equivalently all) $t > 0$.

The energy measure Γ defines in an intrinsic way a pseudo metric ϱ on $(\mathcal{X}, m)$ by

$$\varrho(x,y) = \sup\{f(y) - f(x) : f \in \mathcal{F}, \quad d\Gamma(f,f) \le dm\} \tag{1.18}$$

called the intrinsic metric or Carathéodory metric. We will denote by $B_\varrho(x,r) = \{y \in \mathcal{X} : \varrho(x,y) < r\}$ the open ball with center x and radius r w.r.t. the ϱ metric. Further, we will use the notation

$$\varrho(x,\infty) := \sup\{r > 0 : B_\varrho(x,r) \text{ is relatively compact } \subset \mathcal{X}\}.$$

If $\mathcal{X}$ is a Riemannian manifold and $\mathcal{E}(f,f) = \int |\nabla f|^2 \, d\mu$, then ϱ is just the Riemannian metric.

The pseudo-metric ϱ is not always useful. For some fractal sets such as the Sierpinski carpet the measures $\Gamma(f,f)$ and m are mutually singular – see [Hi]. In these cases the only functions f satisfying the conditions of (1.18) are constants, and so ϱ is identically zero.

The following theorem gives, in the manifold case, the best possible criterion for stochastic completeness in terms of volume growth.

Theorem 1.15 ([Gr1, Gr2, St1]). *Suppose that the metrics ϱ and d on $\mathcal{X}$ are equivalent, and all balls $B_\varrho(x,r)$ are relatively compact. We say that (VGC) holds if for some $x \in \mathcal{X}$,*

$$\int_1^\infty \frac{r}{\log m(B_\varrho(x,r))} dr = \infty. \tag{1.19}$$

If (VGC) holds then $(\mathcal{X}, \mathcal{E})$ is stochastically complete.

Our second main theorem gives a criterion for stochastic completeness, in terms of a balance between the energy of cutoff functions between a sequence of compact sets, and the volume of the regions between these sets.

Theorem 1.16. *Let D_n be an increasing sequence of open sets with compact closure, such that $\cup D_n = \mathcal{X}$. Write $U_n = D_{n+1} - D_n$. Let $\theta_n > 0$ be such that* $\mathrm{CSD}(D_n, D_{n+1}, \theta_n)$ *holds for each n.*
(a) Suppose that $\theta_n \le c_1$ for all n. If

$$\liminf_n \frac{\theta_n m(U_n)}{4^n} = 0 \tag{1.20}$$

then stochastic completeness holds.
(b) Suppose $\theta_n = c_0^2 n^2$, and there exists a constant $b > 0$ such that

$$m(U_n) \le e^{2b(\log n)^2}. \tag{1.21}$$

Then stochastic completeness holds.

Remark 1.17. 1. Note that this Theorem does not involve the intrinsic metric ϱ.
2. We give an example below of a space $\mathcal{X}$ such that for some sufficiently large R_0 one has $\mathcal{X} = B_\varrho(x_0, R_0)$, but which is still stochastically complete.
3. In terms of volume growth, this Theorem gives a weaker criterion than the results of [Gr1, St1]. However since (1.21) only requires that a subsequence of annuli have small volume, there are manifolds for which Theorem 1.16 gives stochastic completeness, while the volume growth criterion of [Gr1, St1] fails.
4. The constant 4 in (1.20) is not best possible; it is related to the choice of 1/8 in (1.17).
5. See Remark 6.1 for the case $\theta_n \asymp n^{2\gamma}$ for $\gamma \in (0, 1)$.

The layout of this paper is as follows. In Section 2 we show how CSA(Ψ) can be used to give a generalization to the space-time scaling Ψ of the 'Davies-Gaffney' bound obtained by Davies in [D]. In Section 3 we use CSA(Ψ) to obtain a Cacciopoli type inequality. This is then used in Section 4 to obtain mean value inequalities, which lead to the upper heat kernel bound UHK(Ψ). In Section 5 we prove that UHK(Ψ) implies CSA(Ψ). Section 6 proves Theorem 1.16, and Section 7 gives examples, based on the 'pre-Sierpinski carpet', of spaces which are geodesically incomplete, or for which the criterion of [Gr1, St1] fails, but which are still stochastically complete.

We write c, c' to denote positive constants which may change on each appearance. Constants denoted c_i will be the same through each argument. Constants related to fundamental properties of the space $\mathcal{X}$ or Dirichlet form, such as those in the volume doubling property, will be denoted $C.$ and will be the same throughout each argument.

Acknowledgment. The authors wish to thank Rich Bass for several conversations on the topic of Remark 1.13(2).

2 Davies Gaffney estimate

We begin by noting the following Cauchy-Schwarz inequality. Let $u, v \in \mathcal{F}$, $f, g \in L^\infty(\mathcal{X}, m)$, and $\lambda > 0$. Then

$$\begin{aligned}\int_{\mathcal{X}} fg\, d\Gamma(u,v) &= \int_{\mathcal{X}} (f/\lambda^{1/2})(\lambda^{1/2} g)\, d\Gamma(u,v)\\ &\le \big(\lambda^{-1}\int_{\mathcal{X}} f^2 d\Gamma(u,u)\big)^{1/2} \cdot \big(\lambda \int_{\mathcal{X}} g^2 d\Gamma(v,v)\big)^{1/2}\\ &\le \frac{1}{2\lambda}\int_{\mathcal{X}} f^2\, d\Gamma(u,u) + \frac{\lambda}{2}\int_{\mathcal{X}} g^2\, d\Gamma(v,v). \qquad (2.1)\end{aligned}$$

Let $D_n, n \ge 0$ be an increasing sequence of open subsets of $\mathcal{X}$ with $\overline{D}_n \subset D_{n+1}$. Suppose that $\mathrm{CSD}(D_n, D_{n+1}, \theta_n)$ holds for each n, and let φ_n be the associated cutoff functions. Let $(a_n, n \ge 0)$ be an increasing sequence, with $a_0 \ge 0$. Set

$$\varphi = a_0 + \sum_{n=0}^{\infty} (a_{n+1} - a_n)(1 - \varphi_n), \qquad (2.2)$$

$$b_n = \frac{(a_{n+1} - a_n)}{a_n}, \qquad b^* = \sup_n b_n, \qquad (2.3)$$

$$C_0 = \sup_n b_n^2 \theta_n. \qquad (2.4)$$

Lemma 2.1. *Suppose D_n, φ_n and φ are as above. Then for any $u \in \mathcal{F}$*

$$\int_{\mathcal{X}} u^2\, d\Gamma(\varphi,\varphi) \le \frac{(b^*)^2}{8}\int_{\mathcal{X}} \varphi^2\, d\Gamma(u,u) + C_0 \int_{\mathcal{X}} \varphi^2 u^2 dm. \qquad (2.5)$$

Proof. Let $U_n = D_{n+1} - D_n$, and note that $a_n \le \varphi \le a_{n+1}$ on U_n. Since $\Gamma(\varphi_n, \varphi_m) = 0$ if $n \ne m$, using CSD,

$$\begin{aligned}\int u^2\, d\Gamma(\varphi,\varphi) &= \sum_n (a_{n+1} - a_n)^2 \int_{U_n} u^2\, d\Gamma(\varphi_n, \varphi_n)\\ &\le \sum_n (a_{n+1} - a_n)^2 \Big(\tfrac{1}{8}\int_{U_n} d\Gamma(u,u) + \theta_n \int_{U_n} u^2 dm\Big)\\ &\le \sum_n b_n^2 \Big(\tfrac{1}{8}\int_{U_n} \varphi^2\, d\Gamma(u,u) + \theta_n \int_{U_n} \varphi^2 u^2 dm\Big),\end{aligned}$$

proving (2.5). □

We can use this to obtain an analogue of Lemma 1 of [D].

Proposition 2.2. *Let φ, a_n, b_n, θ_n and C_0 be as above, and suppose that $b^* \le 1$. Let f have compact support. Set $u_t = P_t f$. Then*

$$\|u_t \varphi\|_2 \le \|f\varphi\|_2 \exp(2C_0 t), \qquad (2.6)$$

$$\int_0^t \int \varphi^2\, d\Gamma(u_s, u_s) ds \le 2\|f\varphi\|_2^2 e^{4C_0 t}. \qquad (2.7)$$

Proof. Given Lemma 2.1 the proof is as in [D]. Let f have compact support and $u_t = P_t f$. Let $N \geq 1$, and set

$$\widetilde{\varphi}_N = a_0 + \sum_{n=0}^{N} (a_{n+1} - a_n)(1 - \varphi_n),$$
$$h_N(t) = ||u_t \widetilde{\varphi}_N||_2^2 = \int u_t^2 \widetilde{\varphi}_N^2 dm.$$

Then since $u_t \in \mathcal{D}(\mathcal{L})$, $\widetilde{\varphi}_N^2 u_t \in \mathcal{F}$,

$$\begin{aligned} h_N'(t) &= 2\langle \mathcal{L} u_t, \widetilde{\varphi}_N^2 u_t \rangle = -2\mathcal{E}(u_t, \widetilde{\varphi}_N^2 u_t) \\ &= -2 \int_{\mathcal{X}} \widetilde{\varphi}_N^2 \, d\Gamma(u_t, u_t) - 4 \int_{\mathcal{X}} \widetilde{\varphi}_N u_t \, d\Gamma(u_t, \widetilde{\varphi}_N). \end{aligned} \tag{2.8}$$

Using (2.1) with $\lambda = 2$ to bound the second term,

$$h_N'(t) \leq - \int_{\mathcal{X}} \widetilde{\varphi}_N^2 \, d\Gamma(u_t, u_t) + 4 \int_{\mathcal{X}} u_t^2 \, d\Gamma(\widetilde{\varphi}_N, \widetilde{\varphi}_N). \tag{2.9}$$

So by Lemma 2.1,

$$\begin{aligned} h_N'(t) &\leq -(1 - \tfrac{1}{2}(b^*)^2) \int_{\mathcal{X}} \widetilde{\varphi}_N^2 \, d\Gamma(u_t, u_t) + 4C_0 \int_{\mathcal{X}} \widetilde{\varphi}_N^2 u_t^2 dm \\ &\leq -\tfrac{1}{2} \int \widetilde{\varphi}_N^2 \, d\Gamma(u_t, u_t) + 4C_0 h_N(t). \end{aligned} \tag{2.10}$$

Thus $h_N' \leq 4C_0 h_N$, and hence $h_N(t) \leq h_N(0) \exp(4C_0 t)$. Integrating (2.10) we obtain

$$h_N(t) - h_N(0) + \tfrac{1}{2} \int_0^t \int \widetilde{\varphi}_N^2 \, d\Gamma(u_s, u_s) \, ds \leq \|f \widetilde{\varphi}_N\|_2^2 \left(e^{4C_0 t} - 1 \right).$$

Letting $N \to \infty$ gives (2.7) and (2.6). $\square$

We can use this to obtain a generalization of the 'Davies-Gaffney' bound in [D].

Proposition 2.3. *Suppose* CSA(Ψ) *holds. Let* $x_1, x_2 \in \mathcal{X}$ *and let* $d(x_1, x_2) = R$. *If* $f_i \in L^2$ *have support in* $A_i = B(x_i, R/4)$ *then*

$$\langle P_t f_1, f_2 \rangle \leq c_1 ||f_1||_2 ||f_2||_2 \exp(-c_2 \Phi(R, t)). \tag{2.11}$$

Here c_i *depend only on* C_S, β *and* β_L.

Proof. First note that

$$\langle P_t f_1, f_2 \rangle \leq \|P_t f_1\|_2 \|f_2\|_2 \leq ||f_1||_2 ||f_2||_2; \tag{2.12}$$

adjusting the constants c_i this is enough to give (2.11) if $\Phi(R, t)$ is small. Next, it is enough to prove (2.11) when $||f_i||_2 = 1$, so we assume this.

Choose $m \geq 1$, let $r = R/2m$, and $D_k = B(x_1, \frac{1}{4}R + kr)$, $k \geq 0$. Let φ_k be cutoff functions for $D_k \subset D_{k+1}$, for $k \geq 0$. Set $a_k = 2^{k \wedge m}$, and define φ as in (2.2). Note that $b^* = (2-1)^2 = 1$, $\theta_k = C_S \Psi(r)^{-1}$, and so $C_0 = C_S \Psi(r)^{-1}$.

Then writing $u_t = P_t f_1$, as in [D, Theorem 2] we have

$$\begin{aligned} \langle P_t f_1, f_2 \rangle &= \langle \varphi P_t f_1, \varphi^{-1} f_2 \rangle \\ &\leq \|\varphi u_t\|_2 \|\varphi^{-1} f_2\|_2 \\ &\leq \|\varphi f_1\|_2 \exp(2 C_S \Psi(r)^{-1} t) \|\varphi^{-1} f_2\|_2 \\ &\leq \exp(2 C_S \Psi(r)^{-1} t) (\sup_{A_1} \varphi)(\sup_{A_2} \varphi^{-1}). \end{aligned} \tag{2.13}$$

The construction of φ gives $\varphi = 1$ on A_1, and $\varphi = 2^m$ on A_2. So

$$\log \langle P_t f_1, f_2 \rangle \leq -\Big(m \log 2 - \frac{2 C_S t}{\Psi(R/m)} \Big) = -\log 2 \Big(m - \frac{c_3 t}{\Psi(R/m)} \Big). \tag{2.14}$$

It remains to choose $m \in \mathbb{N}$ so as to obtain the bound (2.11), and we need to consider several cases.

Case 1. $t \geq \Psi(R)$. By Lemma 1.5 we have $\Phi(R,t) \asymp 1$, and adjusting the constant c_1 we obtain (2.11) from (2.12).

Case 2. $R \leq t \leq \Psi(R)$. Then $R \geq 1$, so we have $R \leq t < R^\beta$. We will choose $m \leq R$, so the final term in (2.14) is

$$m \Big(1 - \frac{c_3 t m^{\beta-1}}{R^\beta} \Big).$$

We wish to choose m so that $c_3 t m^{\beta-1} R^{-\beta} \in [1/3, 2/3]$, and this will be possible provided R^β / t is greater than some constant c_4 (depending only on c_3 and β). We then have $m \asymp (R^\beta/t)^{1/(\beta-1)}$, and hence we obtain the bound (2.11). If $R^\beta/t < c_4$ then $\Phi(R,t) \leq c_5$ and again we obtain (2.11) from (2.12).

Case 3. $t < R$ and $t \leq \Psi(R)$. In this case we will choose $m > R$, so that $\Psi(R/m) = (R/m)^{\beta_L}$. If $R \leq 1$ then $\Psi(R) = R^{\beta_L}$ and so the argument is as in Case 2. If $R > 1$ then $t < R < R^{\beta_L}$, so again we can proceed as in Case 2. $\square$

3 Cacciopoli and mean value inequalities

In this section we prove a mean value inequality as in [Gr0, Section 3]. We begin by seeing that CSA(Ψ) enables us to prove a Cacciopoli inequality similar to [Gr0, Lemma 3.1]. To that aim we need to give a definition of caloric functions in the general context of metric measure spaces.

Definition 3.1. Let I be an interval in $\mathbb{R}$. We say that a function $u : I \to L^2(\mathcal{X}, m)$ is weakly differentiable at $t_0 \in I$ if for any $f \in L^2(\mathcal{X}, m)$ the function $\langle u(t), f \rangle$ is differentiable at t_0. By the principle of uniform boundedness, in this case there is a function $w \in L^2(\mathcal{X}, m)$ such that

$$\lim_{t \to t_0} \Big(\frac{u(t) - u(t_0)}{t - t_0}, f \Big) = \langle w, f \rangle$$

for all $f \in L^2(\mathcal{X}, m)$. We refer to the function w as the weak derivative of the function u at t_0 and write $w = \frac{\partial}{\partial t} u(t_0) = u_t(t_0)$.

Definition 3.2. Consider a function $u : I \to \mathcal{F}$ and let Ω be an open subset of $\mathcal{X}$. We say that u is a caloric function in $I \times \Omega$ if u is weakly differentiable in the space $L^2(\Omega)$ at any $t \in I$ and, for any non-negative $f \in \mathcal{F}_\Omega$ and for any $t \in I$,

$$\langle u_t, f \rangle + \mathcal{E}(u, f) = 0.$$

Lemma 3.3. *(Cacciopoli inequality.) Let $x_0 \in \mathcal{X}$, $B = B(x_0, R)$, $r < R$ and $B' = B(x_0, R-r)$. Suppose that* $\mathrm{CSD}(B', B, \theta)$ *holds, and let φ be the associated cutoff function for $B' \subset B$. Let $T > 0$, and set $Q = B \times (0, T)$. Let $k(t)$ be a Lipschitz function of t with $k(0) = 0$, $0 \le k \le 1$ and $||k'||_\infty = K$. Let $u = u(x,t)$ be a non-negative caloric function, and $v = (u - \theta)_+$, where $\theta > 0$. Set*

$$\eta(x,t) = \varphi(x) k(t).$$

Then

$$\int_B v(x,T)^2 \eta(x,T)^2 m(dx) + \frac{2}{9} \int_Q d\Gamma(\eta v, \eta v)\, dt \le 2(\frac{20}{9}\theta + K) \int_Q v^2\, dm\, dt. \tag{3.1}$$

Proof. Since $k(0) = 0$ we have, writing $v_t = \partial v / \partial t$,

$$\frac{1}{2} \int_B v(x,T)^2 \eta(x,T)^2 m(dx) = \int_Q v v_t \eta^2 dm\, dt + \int_Q v^2 \eta \eta_t\, dm\, dt. \tag{3.2}$$

Using the fact that u is caloric we get

$$\begin{aligned} \int_Q \eta^2 v v_t\, dm\, dt &= \int_Q 1\!\!1_{\{u > \theta\}} \eta^2 v u_t\, dm\, dt = -\int_Q d\Gamma(\eta^2 v, u) \\ &= -\int_Q \eta^2\, d\Gamma(v,v)\, dt - 2\int_Q v\eta\, d\Gamma(v, \eta)\, dt. \end{aligned} \tag{3.3}$$

Further,

$$\int_B d\Gamma(v\varphi, v\varphi) \le 2\int_B \varphi^2\, d\Gamma(v,v) + 2\int_B v^2\, d\Gamma(\varphi, \varphi). \tag{3.4}$$

Let $\lambda > 0$. Then using (2.1)

$$-\int_B \varphi^2\, d\Gamma(v,v) - 2\int_B v\varphi\, d\Gamma(v,\varphi) \le (-1 + \lambda^{-1}) \int_B \varphi^2 d\Gamma(v,v) + \lambda \int_B v^2 d\Gamma(\varphi, \varphi).$$

Taking $\lambda = 2$ and using (3.4) and CSD we obtain

$$\begin{aligned} -\int_B \varphi^2\, d\Gamma(v,v) &- 2\int_B v\varphi\, d\Gamma(v,\varphi) + a\int_B d\Gamma(v\varphi, v\varphi) \\ &\le (-\frac{1}{2} + 2a) \int_B \varphi^2\, d\Gamma(v,v) + (2 + 2a) \int_B v^2 d\Gamma(\varphi, \varphi) \\ &\le (-\frac{1}{2} + 2a + (2+2a)\frac{1}{8}) \int_B \varphi^2 d\Gamma(v,v) + (2+2a)\theta \int_B v^2\, dm \\ &= \frac{20}{9}\theta \int_B v^2\, dm \end{aligned} \tag{3.5}$$

if $a = 1/9$. Multiplying this inequality by $k(t)^2$ and integrating gives

$$\begin{aligned}-\int_Q \eta^2 \, d\Gamma(v,v)\, dt - 2\int_Q v\eta \, d\Gamma(v,\eta)\, dt + \frac{1}{9}\int_Q d\Gamma(v\eta, v\eta)\, dt \\ \leq \frac{20}{9}\theta \int_0^T \int_B v^2 k(t)^2 \, dm\, dt \leq \frac{20}{9}\theta \int_Q v^2 \, dm\, dt.\end{aligned}$$

Combining this with (3.2) and (3.3) we obtain

$$\begin{aligned}\int_B v(x,T)^2 \eta(x,T)^2 \, m(dx) + \frac{2}{9}\int_Q d\Gamma(v\eta, v\eta)\, dt \\ \leq 2\int_Q v^2 \eta\eta_t \, dm\, dt + \frac{40}{9}\theta \int_Q v^2 \, dm\, dt \\ \leq (2K + \frac{40}{9}\theta) \int_Q v^2 \, dm\, dt.\end{aligned}$$

In the final line we used the fact that $\eta \leq 1$. □

Remark 3.4. Note that to obtain (3.5) we needed that the constant in the first term on the right of (1.17) was less than 1/4.

The key step in the proof of the mean value inequality is the following comparison over cylinders. For a cylinder $Q \subset \mathcal{X} \times \mathbb{R}_+$ and a function w write

$$I(w,Q) = \int_Q w^2 \, dm\, dt.$$

Lemma 3.5. *(See [Gr0, Lemma 3.2].) Suppose* FK(Ψ) *and* CSA(Ψ) *hold. Let $\widetilde{u}$ be a caloric function in $Q = B(x_0,R) \times (0,T)$. Let $u = \widetilde{u}_+$, $\theta > 0$ and $v = (u-\theta)_+$. Let $0 < T_1 < T$, $R_1 \in (\frac{1}{2}R, R)$, $Q_1 = B(x_0,R_1) \times (T_1,T)$,*

$$I = I(u,Q), \quad I_1 = I(v,Q_1),$$

and $\delta = T_1 \wedge \Psi(R - R_1)$. Then

$$I_1 \leq \frac{c_1 I^{1+\nu} \Psi(R)}{\delta^{1+\nu} \theta^{2\nu} \, m(B)^{\nu}}. \tag{3.6}$$

Proof. Let $B = B(x_0,R)$, $B' = B(x_0, \frac{1}{2}(R+R_1))$ and $B_1 = B(x_0,R_1)$. Set

$$D_t = \{x \in B' : u(x,t) > \theta\}.$$

Let φ be a cutoff function for $B_1 \subset B'$, $k(t) = 1 \wedge (t/T_1)$, and $\eta(x,t) = \varphi(x)k(t)$.

As in [Gr0] the proof uses five inequalities:

$$\int_{B'} u(x,t_0)^2\,dm \le c_0\delta^{-1}\int_Q u^2\,dm\,dt \ \text{ for } t_0\in(T_1,T), \tag{3.7}$$

$$\int_Q d\Gamma(v\eta,v\eta)\,dt \le c_0\delta^{-1}\int_Q u^2\,dm\,dt, \tag{3.8}$$

$$\int_B d\Gamma(v\eta,v\eta) \ge \lambda_1(D_t)\int_B v^2\eta^2\,dm \ \text{ for } t\in(0,T), \tag{3.9}$$

$$\lambda_1(D_t) \ge C_F m(B)^\nu \Psi(R)^{-1} m(D_t)^{-\nu}, \tag{3.10}$$

$$m(D_t) \le \theta^{-2}\int_{B'} u(x,t)^2\,dm. \tag{3.11}$$

Of these, (3.9) is immediate from the variational definition of λ_1, (3.10) is the Faber-Krahn inequality (1.8), and (3.11) is just Markov's inequality. So it remains to prove (3.7) and (3.8).

The inequality (3.8) is immediate from (3.1). Since $\|k'\|_\infty = 1/T_1$ we have the constant on the right side of (3.1) is $c(\Psi(R-R_1)^{-1}+T_1^{-1}) \le c'\delta^{-1}$. So

$$\frac{2}{9}\int_Q d\Gamma(v\eta,v\eta)\,dt \le c\delta^{-1}\int_Q u^2\,dm\,dt.$$

For (3.7) let $\widetilde{\varphi}$ be a cutoff function for $B' \subset B$ and $\widetilde{\eta}(x,t) = \widetilde{\varphi}(x)k(t)$. Then by (3.1) applied to u in the cylinder $Q_t = B\times(0,t)$,

$$\int_B u(x,t)^2\widetilde{\eta}(x,t)^2 m(dx) \le c\delta^{-1}\int_{Q_t} u^2\,dm\,dt \le c\delta^{-1}\int_Q u^2\,dm\,dt.$$

The rest of the argument is as in [Gr0]. □

4 Heat kernel upper bounds

These bounds can now be proved by the methods of [CG], which in turn uses ideas in [Gr0]. Since [CG] is written in the graph context, and both of these papers just consider the case $\Psi(r) = r^2$, we give details. In particular we need to be more careful in our handling of exceptional sets; issues with these do not arise for the manifolds or graphs treated in [Gr0, CG]. Note that VD implies that there exists a constant $\alpha < \infty$ such that

$$\frac{V(x,R)}{V(y,r)} \le C_G\Big(\frac{d(x,y)+R}{r}\Big)^\alpha, \quad 0<r<R,\ x,y\in\mathcal{X}. \tag{4.1}$$

Define the measure $\widetilde{m}(dx,ds) = m(dx)ds$ on $\mathcal{X}\times\mathbb{R}$. Given a cylinder $Q\subset\mathcal{X}\times\mathbb{R}$ and $u: Q\to\mathbb{R}$ we write $\operatorname{ess\,sup} u$ for the essential supremum with respect to the measure $\widetilde{m}$.

Define

$$\beta_2 = \beta_L \vee \beta, \quad \beta_1 = \beta_L\wedge\beta, \tag{4.2}$$

and note that if $0 < r < R$,

$$\Big(\frac{R}{r}\Big)^{\beta_1} \le \frac{\Psi(R)}{\Psi(r)} \le \Big(\frac{R}{r}\Big)^{\beta_2}, \quad \Big(\frac{R}{r}\Big)^{1/\beta_2} \le \frac{\Psi^{-1}(R)}{\Psi^{-1}(r)} \le \Big(\frac{R}{r}\Big)^{1/\beta_1}. \tag{4.3}$$

Write

$$F(R,T) = \frac{T}{\Psi(R)} \vee \Big(\frac{\Psi(R)}{T}\Big)^{\alpha/\beta_1}. \tag{4.4}$$

Proposition 4.1. *(L^2 Mean value inequality). Set $Q = B(x_0,R) \times (0,T)$. Assume* CSA($\Psi$) *and* FK($\Psi$) *hold, and let $u \ge 0$ be caloric in Q. Then if $Q_\infty = B(x_0,R/2) \times (T/2,T)$,*

$$\text{ess sup}_{Q_\infty} u(x,s)^2 \le \frac{c_0 F(R,T)}{TV(x_0,R)} \int_Q u(x,s)^2 \widetilde{m}(dx,ds). \tag{4.5}$$

Proof. (See the proof of [Gr0, Theorem 3.1].) It is sufficient to consider the case $T = \Psi(R)$. Indeed, suppose (4.5) holds in this case, and let $T = \lambda\Psi(R)$.

If $\lambda \in (0,1)$ let r be such that $\Psi(r) = T$. We can cover $B' = B(x_0,R/2)$ by balls $B(z_i,r/2)$ such that each $B(z_i,r) \subset B(x_0,R)$. Let $Q_i = B(z_i,r) \times (0,T)$, and $Q_{i,\infty} = B(z_i,r/2) \times (T/2,T)$. Note that by (4.3)

$$\frac{V(x_0,R)}{V(x_0,r)} \le C_G\Big(\frac{R}{r}\Big)^{\alpha} = C_G\Big(\frac{\Psi^{-1}(T/\lambda)}{\Psi^{-1}(T)}\Big)^{\alpha} \le C_G\lambda^{-\alpha/\beta_1}. \tag{4.6}$$

Then

$$\text{ess sup}_{Q_\infty} u(x,s)^2 \le \max_i \text{ess sup}_{Q_{i,\infty}} u(x,s)^2,$$

and for each i, using (4.6),

$$\begin{aligned}\text{ess sup}_{Q_{i,\infty}} u(x,s)^2 &\le \frac{c_0}{TV(x_0,r)} \int_{Q_i} u^2 d\widetilde{m} \\ &\le \frac{c_0}{TV(x_0,R)} \frac{V(x_0,R)}{V(x_0,r)} \int_Q u^2 d\widetilde{m} \\ &\le \frac{c_0 C_G \lambda^{-\alpha/\beta_1}}{TV(x_0,R)} \int_Q u^2 d\widetilde{m}.\end{aligned}$$

Similarly if $T = \lambda\Psi(R)$ with $\lambda > 1$ then applying (4.5) to a sequence of cylinders $(T_i - \Psi(R), T_i) \times B(x_0,R)$ one obtains

$$\text{ess sup}_{Q_\infty} u(x,s)^2 \le \frac{c_0\lambda}{TV(x_0,R)} \int_Q u(x,s)^2 d\widetilde{m}.$$

Now let $T = \Psi(R)$. Let δ_k, $k = 0,1,\dots$ be a sequence to be chosen later, and let (r_k) and (t_k) be sequences such that $r_0 = R$, $t_0 = 0$,

$$\delta_{k+1} = \Psi(r_k - r_{k+1}) = t_{k+1} - t_k, \tag{4.7}$$

and

$$R = r_0 > r_1 > \cdots > r_k > \cdots > R/2, \quad 0 = t_0 < t_1 < \cdots < t_k < \cdots < T/2. \tag{4.8}$$

Let $Q_k = B(x_0, r_k) \times (t_k, T)$. Let $\theta > 0$ (also to be chosen later) and set $\alpha_k = (1-2^{-k})\theta$, $u_k = (u - \alpha_k)_+$, and

$$I_k = \int_{Q_k} u_k^2 d\widetilde{m}.$$

Let $\theta_k = \alpha_{k+1} - \alpha_k$. Then by (3.6) applied to the function u_k in $Q_{k+1} \subset Q_k$,

$$I_{k+1} \le I_k \, \frac{c_1 I_k^\nu \Psi(r_k)}{\delta_{k+1}^{1+\nu} \theta_k^{2\nu} m(B(x_0, r_k))^\nu} \le I_k \, \frac{c_2 \Psi(R) 2^{2\nu(k+1)} I_k^\nu}{V(x_0, R)^\nu \theta^{2\nu} \delta_{k+1}^{1+\nu}}. \tag{4.9}$$

Let $A = c_2 \Psi(R) 4^\nu / V(x_0, R)^\nu \theta^{2\nu}$. Now choose $M \ge 2$ and $b > 4$ such that $M^{1/\beta_2} \ge 2$, and $(4/b)^{1/(1+\nu)} = M^{-1}$. Choose δ_{k+1} such that

$$\frac{A 2^{2\nu k} I_k^\nu}{\delta_{k+1}^{1+\nu}} = b^{-1}, \quad k = 0, 1, \ldots \tag{4.10}$$

With this choice of (δ_k) we have $I_k \le b^{-k} I_0$, and consequently

$$\delta_{k+1} = (Ab 4^{k\nu} I_k^\nu)^{1/(1+\nu)} \le (Ab I_0^\nu)^{1/(1+\nu)} (4/b)^{k\nu/(1+\nu)} = A_1 M^{-k}, \tag{4.11}$$

where $A_1 = (Ab I_0^\nu)^{1/(1+\nu)}$. In order that the condition (4.8) should hold, we need

$$\sum_{k=1}^\infty \delta_k \le T/2, \tag{4.12}$$

$$\sum_{k=1}^\infty \Psi^{-1}(\delta_k) \le R/2. \tag{4.13}$$

We have

$$\sum_{k=1}^\infty \Psi^{-1}(\delta_k) \le \sum_{k=1}^\infty \Psi^{-1}(A_1 M^{-k}) \le c_3 \Psi^{-1}(A_1) \sum_{k=1}^\infty M^{-k/\beta_2} \le 2 c_3 \Psi^{-1}(A_1),$$

and

$$\sum_{k=1}^\infty \delta_k \le 2 A_1.$$

So for (4.8) to hold it is enough that

$$A_1 = \Big(\frac{c_2 4^\nu b I_0^\nu \Psi(R)}{V(x_0, R)^\nu \theta^{2\nu}} \Big)^{1/(1+\nu)} \le (T/4) \wedge \Psi(R/4c_3).$$

For this it is enough if θ is chosen large enough so that

$$\frac{I_0^\nu \Psi(R)}{V(x_0, R)^\nu \theta^{2\nu}} \le c_4 \Psi(R)^{1+\nu},$$

and so we can take

$$\theta^2 = \frac{c_5 I_0}{\Psi(R) V(x_0, R)}. \tag{4.14}$$

We then have $I_k \to 0$ as $k \to \infty$, and hence

$$\int_{Q_\infty} (u(x,s) - \theta)_+^2 \widetilde{m}(dx, ds) \le \inf_k I_k = 0, \tag{4.15}$$

which implies that $u(x,s) \le \theta \ \widetilde{m}$ a.e. on Q_∞. $\square$

We now give an L^1 mean value inequality.

Proposition 4.2. *(L^1 Mean value inequality). Assume* FK(Ψ) *and* CSA(Ψ) *hold. Let $R > 0$, $T = \Psi(R)$, let $Q = B(x_0, R) \times (0, T)$, and let $u \ge 0$ be caloric in Q. Then writing $Q' = B(x_0, 2R/3) \times (T/2, T)$,*

$$\text{ess sup}_{\,Q'} u(x,s) \le \frac{c_1 F(R,T)}{T V(x_0, R)} \int_Q u(x,s) \widetilde{m}(dx, ds). \tag{4.16}$$

Proof. This follows from the L^2 mean value inequality by quite general arguments, which use only VD – see p. 688-691 of [CG]. As with Proposition 4.1, it is enough to consider the case $T = \Psi(R)$. $\square$

In order to obtain heat kernel bounds from the mean value theorem, we need better control of the exceptional set. We will use regularity results from [GT], and to use these we need to consider the killed heat kernel. For $D \subset \mathcal{X}$ write (P_t^D) for the semigroup of X killed on exiting D. Then if FK(Ψ) holds, by [GH, Lemma 5.5] the semigroup (P_t^D) is ultracontractive, that is there exists a left continuous function $\gamma(t)$ such that

$$||P_t^D f||_\infty \le \gamma(t) ||f||_1, \quad t > 0, f \in L^1(\mathcal{X}) \cap L^2(\mathcal{X}).$$

(In fact we have $\gamma(t) = c(at)^{-1/\nu}$ with $a = a(n) = m(D_n)^\nu / \Psi(nR)$). Consequently we will be able to use [GT, Theorem 2.12] to obtain estimates which hold on $\mathcal{X} - \mathcal{N}$, where $\mathcal{N}$ is a properly exceptional set.

Lemma 4.3. *Assume* FK(Ψ) *and* CSA(Ψ)*. Let $x_0, x_1 \in \mathcal{X}_0$, $T > 0$, $0 < t \le T$, and $r = \Psi(t)$. Let $R_0 > R$ and $D = B(x_0, R_0)$. Then for m-a.a. $y \in B(x_0, r/2)$,*

$$p_T^D(x_1, y) \le \frac{c_1}{t V(x_0, r)} \int_{T-t/2}^{T+t/2} \int_{B(x,r)} p_s^D(x_1, y') \widetilde{m}(dy', ds). \tag{4.17}$$

Proof. Set $Q = B(x_0, r) \times (T - t/2, T + t/2)$, and $Q' = B(x_0, r/2) \times (T, T + t/2)$. Since $u(y,s) = p_s^D(x_1, y)$ is caloric in Q, by Proposition 4.2

$$\text{ess sup}_{\,(y,s) \in Q'} p_s^D(x_1, y) \le \frac{c_1}{t V(x_0, r)} \int_Q p_s^D(x_1, y') \widetilde{m}(dy', ds). \tag{4.18}$$

Setting

$$A = \frac{c_1}{tV(x_0,r)} \int_Q p_s^D(x_1,y')\widetilde{m}(dy',ds), \tag{4.19}$$

the right side of (4.18) is bounded by A.

Thus there exists a subset $I \subset (T, T+t/2)$ of full measure such that if $T' \in I$ then

$$p_{T'}^D(x_1,y) \le A, \qquad \text{for } m\text{-a.a. } y \in B(x_0,r/2)\ .$$

Write $g(y) = p_T^D(x_1,y)$. Then the L^2-continuity of (P_t^D) implies that $P_h^D g \to g$ m-a.e. as $h \to 0$. Taking the limit along a sequence h_k such that $T + h_k \in I$ for each k, it follows that $p_T^D(x_1,y) \le A$ for m-a.a. $y \in B(x_0,r/2)$. □

Theorem 4.4. *Assume VD, FK(Ψ), and* CSA(Ψ) *hold. Then UHK(Ψ) holds.*

Proof. We use the argument of [CG], but need extra care because of exceptional sets. Fix $x_0, y_0 \in \mathcal{X}_0$, $T > 0$, and let $R = d(x,y)$. Let $R_0 > 4R$, and let $D = B(x_0,R_0)$. Set $T_0 = T/2$ and $r = \Psi^{-1}(T_0)$. Let $Q(z) = B(z,r)\times(T-T_0/2, T+T_0/2)$. Let $r' < R/4 \wedge r/2$, and g_1 and g_2 be non-negative bounded functions with supports in $B(x_0,r')$ and $B(y_0,r')$ respectively, such that $\int g_1 = \int g_2 = 1$. Set

$$I = \iint p_T^D(x,y) g_1(x) g_2(y) m(dx)m(dy).$$

Let $x \in B(x_0,R/4)$. Then applying (4.17) to the caloric function $u(y,s) = p_s^D(x,y)$ in $Q(y_0)$, we have

$$p_T^D(x,y) \le \frac{c_1}{T_0 V(y_0,r)} \int_{T-T_0/2}^{T+T_0/2} \int_{B(y_0,r)} p_s^D(x,y')\widetilde{m}(dy',ds) \tag{4.20}$$

for m-a.a. $y \in B(y_0,r/2)$. Hence

$$\begin{aligned} I &\le \frac{c_1}{T_0V(y_0,r)} \iint g_1(x)g_2(y)m(dx)m(dy) \int_{Q(y_0)} p_s^D(x,y')\widetilde{m}(dy',ds) \\ &= \frac{c_1}{T_0V(y_0,r)} \int_{B(y_0,r)} \int_{T-T_0/2}^{T+T_0/2} \int g_1(x) p_s^D(x,y')\widetilde{m}(dy',ds)m(dx). \end{aligned} \tag{4.21}$$

If $y' \in B(y_0,r)$ and $s \in (T-T_0/2, T+T_0/2)$, then by considering the cylinder $B(x_0,r) \times (s-T_0/2, s+T_0/2)$, we have by (4.17), for m-a.a. $x \in B(x_0,r/2)$,

$$\begin{aligned} p_s^D(y',x) &\le \frac{c_1}{T_0V(x_0,r)} \int_{s-T_0/2}^{s+T_0/2} \int_{B(x_0,r)} p_{s'}^D(y',x')\widetilde{m}(dx',ds') \\ &\le \frac{c_1}{T_0V(x_0,r)} \int_{T-T_0}^{T+T_0} \int_{B(x_0,r)} p_{s'}^D(x',y')\widetilde{m}(dx',ds'), \end{aligned}$$

Substituting this into the final term in (4.21), we obtain

$$\begin{aligned} I &\le \frac{c_1^2}{T_0^2 V(y_0,r)V(x_0,r)} \int_{B(y_0,r)} m(dy') \int_{T-T_0/2}^{T+T_0/2} ds \\ &\qquad \times \int m(dx) g_1(x) \int_{T-2T_0}^{T+2T_0} ds' \int_{B(x_0,r)} m(dx') p^D_{s'}(x',y') \\ &= \frac{c_1^2}{T_0 V(y_0,r)V(x_0,r)} \int_{B(y_0,r)} m(dy') \int_{B(x_0,r)} m(dx') \int_{T-T_0}^{T+T_0} ds' p^D_{s'}(x',y') \\ &\le \frac{2c_1^2}{TV(y_0,r)V(x_0,r)} \int_{T/2}^{3T/2} \langle P_s f_x, f_y \rangle ds, \end{aligned} \tag{4.22}$$

where $f_x = 1_{B(x_0,r)}$ and $f_y = 1_{B(y_0,r)}$.

If $r < R/4$ then the Davies Gaffney bound Proposition 2.3 implies that for $T/2 \le s \le 2T$,

$$\begin{aligned} \langle P_s f_x, f_y \rangle &\le c_2 V(x_0,r)^{1/2} V(y_0,r)^{1/2} \exp(-c_2 \Phi(R,s)) \\ &\le c_2 V(x_0,r)^{1/2} V(y_0,r)^{1/2} \exp(-c_3 \Phi(R,T)). \end{aligned} \tag{4.23}$$

If $r \ge R/4$ we still have by (2.12)

$$\langle P_s f_x, f_y \rangle \le ||P_t f_x||_2 ||f_y||_2 \le V(x_0,r)^{1/2} V(y_0,r)^{1/2}. \tag{4.24}$$

As $r \ge R/4$ we have $T > c\Psi(R)$ and so $\Phi(R,T) \le c'$ by Lemma 1.5, and the exponential in (4.23) is of order 1. Adjusting the constant c_2 we therefore obtain, in both cases,

$$\langle P_s f_x, f_y \rangle \le c_2 V(x_0,r)^{1/2} V(y_0,r)^{1/2} \exp(-c_3 \Phi(R,T)). \tag{4.25}$$

Now set

$$\widetilde{V}(x,r) = r^{-1} \int_r^{2r} V(x,s) ds.$$

Then $\widetilde{V}(x,r) \asymp V(x,r)$, and the function $x \to \widetilde{V}(x,r)$ is continuous. Set

$$H_t(x,y) = c_4 \widetilde{V}(x, \Psi^{-1}(t))^{1/2} \widetilde{V}(y, \Psi^{-1}(t))^{1/2} \exp(-c_3 \Phi(d(x,y),t)).$$

Then from (4.25) and (4.22) we deduce that $p^D_T(x,y) \le H_T(x_0,y_0)$, for $m \times m$ a.a. (x,y) in a neighbourhood of (x_0,y_0). It follows that $p^D_T(x,y) \le H_T(x,y)$ for $m \times m$ a.a. (x,y).

Now let $D \uparrow \mathcal{X}$; then since P^D is ultracontractive it follows from [GT, Theorem 2.12(c)] that

$$p_t(x,y) \le H_t(x,y) \quad \text{for } m \times m \text{ a.a. } (x,y) \text{ and all } t > 0.$$

Since the function H_t is continuous, by [GT, Theorem 2.12(d)] there exists a properly exceptional set $\mathcal{N}_1$ such that if $\mathcal{X}_1 = \mathcal{X} - \mathcal{N}_1$ then

$$p_t(x,y) \le H_t(x,y) \quad \text{for } (x,y) \in \mathcal{X}_1 \times \mathcal{X}_1 \text{ and all } t > 0, \tag{4.26}$$

which proves UHK(Ψ). □

5 Proof of CSA from upper heat kernel bounds

In this section we prove the implication (2) ⇒ (1) of Theorem 1.12. We assume throughout this section that $\mathcal{X}$ is unbounded, and satisfies VD and UHK(Ψ).

We begin by seeing that it is enough to prove (1.17) in a slightly weaker form.

Lemma 5.1. *Let $\mathcal{X}$ satisfy VD. Suppose that there exists constants c_1, c_2 such that for all $x \in \mathcal{X}$, $R > 0$ and $r > 0$ there exists a cutoff function φ for $B(x,R) \subset B(x, r+R)$ such that, if $U = B(x, R+r) - B(x,R)$ and $f \in \mathcal{F}$, then*

$$\int_U f^2 \, d\Gamma(\varphi,\varphi) \le c_1 \int_U d\Gamma(f,f) + c_2 \Psi(r)^{-1} \int_U f^2 dm. \tag{5.1}$$

Then $\mathcal{X}$ satisfies CSA(Ψ).

Proof. Let $x \in \mathcal{X}$, $R > 0$ and $r > 0$ and $B' = B(x,R)$, $B = B(x, R+r)$; we will construct a cutoff function φ for $B' \subset B$ which satisfies (1.17) with $\theta = c\Psi(r)^{-1}$.

Let $\lambda > 0$, and let

$$s_n = c_0 r e^{-n\lambda/\beta_2},$$

where $c_0 = c_0(\lambda)$ is chosen so that $\sum_{n=1}^\infty s_n = r$ and β_2 is as in (4.2). Set $r_0 = 0$,

$$r_n = \sum_{k=1}^n s_k,$$

so that $R < R + r_1 < R + r_2 < \cdots < R + r$. Let $B_n = B(x_0, R + r_n)$, and $U_n = B_{n+1} - B_n$. By hypothesis there exists a cutoff function φ_n for $B_n \subset B_{n+1}$ satisfying

$$\int_{U_n} f^2 \, d\Gamma(\varphi_n,\varphi_n) \le c_1 \int_{U_n} d\Gamma(f,f) + c_2 \Psi(s_{n+1})^{-1} \int_{U_n} f^2 dm. \tag{5.2}$$

Let $b_n = e^{-n\lambda}$ and set

$$\varphi = \sum_{n=1}^\infty (b_{n-1} - b_n)\varphi_n. \tag{5.3}$$

Then $\varphi = 0$ on B^c, and $\varphi = 1$ on B', so φ is a cutoff function for $B' \subset B$. On U_n we have

$$\varphi = (b_{n-1} - b_n)\varphi_n + b_n,$$

and so $b_n \le \varphi \le b_{n-1}$ on U_n. Hence on U_n

$$b_{n-1} - b_n \le \frac{\varphi(b_{n-1} - b_n)}{b_n} = (e^\lambda - 1)\varphi. \tag{5.4}$$

Now if $f : B \to \mathbb{R}$ then by (5.2)

$$\begin{aligned}\int_B f^2 \, d\Gamma(\varphi,\varphi) &= \sum_{k=1}^\infty (b_{k-1} - b_k)^2 \int_{U_k} f^2 d\Gamma(\varphi_k,\varphi_k) \\ &\le c_1 \sum_{k=1}^\infty (b_{k-1} - b_k)^2 \int_{U_k} d\Gamma(f,f) + c_2 \sum_{k=1}^\infty (b_{k-1} - b_k)^2 \Psi(s_{k+1})^{-1} \int_{U_k} f^2 dm.\end{aligned}$$

Using (5.4) we have

$$c_1 \sum_{k=1}^{\infty} (b_{k-1} - b_k)^2 \int_{U_k} d\Gamma(f,f) \le c_1 (e^{\lambda} - 1)^2 \sum_{k=1}^{\infty} \int_{U_k} \varphi^2 d\Gamma(f,f)$$
$$\le c_1 (e^{\lambda} - 1)^2 \int_U \varphi^2 d\Gamma(f,f). \tag{5.5}$$

Now using (4.3) and (5.4)

$$\frac{\Psi(r)}{\Psi(s_{k+1})} \le \Big(\frac{r}{c_0(\lambda) r e^{-(k+1)\lambda/\beta_2}} \Big)^{\beta_2} = \frac{e^{\lambda} e^{k\lambda}}{c_0(\lambda)^{\beta_2}} = \frac{e^{\lambda}(e^{\lambda} - 1)}{c_0(\lambda)^{\beta_2} (b_{k-1} - b_k)}.$$

Therefore

$$(b_{k-1} - b_k) \Psi(s_{k+1})^{-1} \le c_3(\lambda) \Psi(r)^{-1},$$

and hence

$$c_2 \sum_{k=1}^{\infty} \int_{U_k} (b_{k-1} - b_k)^2 \Psi(s_{k+1})^{-1} f^2 dm \le c_2 c_3(\lambda) \Psi(r)^{-1} \sum_{k=1}^{\infty} \int_{U_k} f^2 (b_{k-1} - b_k) dm$$
$$\le c_2 c_3(\lambda) \Psi(r)^{-1} \int_U f^2 (e^{\lambda} - 1) \varphi dm. \tag{5.6}$$

Thus

$$\int_U f^2 \, d\Gamma(\varphi,\varphi) \le c_1 (e^{\lambda} - 1)^2 \int_U \varphi^2 d\Gamma(f,f) + c_4(\lambda) \Psi(r)^{-1} \int_U f^2 \varphi dm. \tag{5.7}$$

We now choose λ so that $c_1^2 (e^{\lambda} - 1)^2 = 1/8$ and since $\varphi \le 1$ we obtain (1.17). □

Corollary 5.2. *Let $\mathcal{X}$ satisfy VD. Then the condition* CSA(Ψ) *is stable.*

Proof. Let $(\mathcal{E}_i, \mathcal{F})$, $i = 1, 2$ be two Dirichlet forms on $L^2(\mathcal{X}, m)$ satisfying the hypothesis of Lemma 1.1, and suppose that CSA(Ψ) holds for $\mathcal{E}_1$. Let $B' = B(x, R) \subset B = B(x, R + r)$, and let φ be a cutoff function for $B' \subset B$. Then by Lemma 1.1, if $f \in \mathcal{F}$, $U = B - B'$,

$$\int_U f^2 \, d\Gamma^{(2)}(\varphi,\varphi) \le C \int_U f^2 \, d\Gamma^{(1)}(\varphi,\varphi)$$
$$\le (C/8) \int_U \varphi^2 d\Gamma^{(1)}(f,f) + C C_S \Psi(r)^{-1} \int_U f^2 dm$$
$$\le (C^2/8) \int_U d\Gamma^{(2)}(f,f) + C C_S \Psi(r)^{-1} \int_U f^2 dm.$$

Thus $(\mathcal{X}, \mathcal{E}_2)$ satisfies the condition (5.1) and so by Lemma 5.1 CSA(Ψ) holds for $\mathcal{E}_2$. □

Now let $(X_t, t \in \mathbb{R}_+, \mathbb{P}^x, x \in \mathcal{X})$ be the Hunt process associated with the semigroup P_t and Dirichlet form $\mathcal{E}$. Recall the definition of $\mathcal{X}_0$ from Section 1. For a set $D \subset \mathcal{X}$ define the exit time

$$\tau_D = \inf\{t > 0 : X_t \in D^c\}. \tag{5.8}$$

Lemma 5.3. *Suppose $\mathcal{X}$ satisfies VD and* UHK(Ψ). *There exists a constant $\varepsilon > 0$ such that for all $x \in \mathcal{X}_0$ and $r > 0$,*

$$\mathbb{P}^x(\tau_{B(x,r)} \le \varepsilon \Psi(r)) \le \varepsilon.$$

Proof. In the case $\Psi(r) = r^\beta$ this property is denoted P_β in [GH], and the result follows by [GH, Theorem 2.2]. The general case is similar. □

For $D \subset \mathcal{X}$, $\lambda > 0$ set

$$G_\lambda^D f(x) = \mathbb{E}^x \int_0^{\tau_D} e^{-\lambda t} f(X_t)dt.$$

Lemma 5.4. *Suppose $\mathcal{X}$ satisfies VD and* UHK(Ψ). *Let $x_0 \in \mathcal{X}$, $r > 0$, $R > 0$, and define the annuli $D_0 = B(x_0, R+9r/10) - \overline{B}(x_0, R+r/10)$, $D_1 = B(x_0, R+4r/5) - \overline{B}(x_0, R+r/5)$, $D_2 = B(x_0, R+3r/5) - \overline{B}(x_0, R+2r/5)$. Let $\lambda = \Psi(r)^{-1}$, and set*

$$h = G_\lambda^{D_0} 1_{D_1}. \tag{5.9}$$

Then h has support $\overline{D}_0$, $h \in \mathcal{F}_{D_0}$ and satisfies

$$h(x) \le \Psi(r) \quad \text{for all } x \in \mathcal{X}, \tag{5.10}$$

$$h(x) \ge c_1^{-1}\Psi(r) \quad \text{for } x \in D_2 \cap \mathcal{X}_0. \tag{5.11}$$

Proof. That $h \in \mathcal{F}_{D_0}$ follows by [FOT, Theorem 4.4.1]. The definition of h implies that $h(x) = 0$ for $x \notin \overline{D}_0$, and the upper bound on h is elementary, since $h \le G_\lambda^{\mathcal{X}} 1 = \lambda^{-1}$.

Now let $\varepsilon > 0$ be as in Lemma 5.3. Let $r_0 = r/5$, $x \in D_2$, and $B_1 = B(x, r_0) \subset D_1$. Let $s = \varepsilon\Psi(r_0)$, and ξ_λ be an exponential r.v. independent of X with mean λ^{-1}. Then

$$\begin{aligned} h(x) &\ge \mathbb{E}^x \int_0^{\xi_\lambda \wedge \tau_{D_0}} 1_{D_1}(X_t)\,dt \ge \mathbb{E}^x \int_0^{\xi_\lambda \wedge \tau_{B_1}} 1_{B_1}(X_t)\,dt \\ &\ge s\mathbb{P}^x(\xi_\lambda \wedge \tau_{B_1} \ge s) = s\mathbb{P}^x(\tau_{B_1} > s, \xi_\lambda > s) \\ &= s\mathbb{P}^x(\tau_{B_1} > s)\mathbb{P}^x(\xi_\lambda > s) \ge s(1-\varepsilon)e^{-\lambda s}, \end{aligned}$$

which yields (5.11). □

Theorem 5.5. *Suppose $\mathcal{X}$ satisfies VD and* UHK(Ψ). *Then $\mathcal{X}$ satisfies* FK(Ψ) *and* CSA(Ψ).

Proof. The proof that UHK(Ψ) plus VD implies FK(Ψ) is as in Section 5.5 of [GH], where the case $\Psi(r) = r^\beta$ is given.

To prove CSA(Ψ) we will show that $\mathcal{X}$ satisfies the hypotheses of Lemma 5.1. So let $B' = B(x_0, R)$ and $B = B(x_0, R+r)$, and $U = B - B'$, and let D_i, h be as in Lemma 5.4. Set

$$g(x) = \frac{c_1 h(x)}{\Psi(r)}, \tag{5.12}$$

$$\varphi(x) = \begin{cases} 1 \wedge g(x) & \text{if } x \in B(x_0, R+r/2)^c, \\ 1 & \text{if } x \in B(x_0, R+r/2). \end{cases} \tag{5.13}$$

Then by Lemma 5.4 $\varphi = 0$ on B^c, and $\varphi = 1$ on B', so it remains to verify the inequality (5.1).

Let $f \in \mathcal{F}$. Since g is zero outside U we have

$$\begin{aligned}\int_U f^2 d\Gamma(\varphi,\varphi) \le \int_U f^2 d\Gamma(g,g) &= \int_{\mathcal{X}} f^2 d\Gamma(g,g) \\ &= \int_{\mathcal{X}} d\Gamma(f^2 g, g) - 2\int_{\mathcal{X}} fg d\Gamma(f,g). \qquad (5.14)\end{aligned}$$

Now writing $\mathcal{E}_\lambda(u,v) = \mathcal{E}(u,v) + \lambda\langle u,v\rangle$,

$$\begin{aligned}\int_{\mathcal{X}} d\Gamma(f^2 g, g) = \mathcal{E}(f^2 g, g) &\le \mathcal{E}_\lambda(f^2 g, g) \\ &= c_1 \Psi(r)^{-1} \mathcal{E}_\lambda(f^2 g, G_\lambda^{D_0} 1_{D_1}) \\ &= c_1 \Psi(r)^{-1} \langle f^2 g, 1_{D_1}\rangle \le c_1 \Psi(r)^{-1} \int_U f^2 g dm. \qquad (5.15)\end{aligned}$$

Here we used [FOT, Theorem 4.4.1] and the fact that $f^2 g \in \mathcal{F}_{D_0}$ to obtain the third line. By (2.1),

$$\Big|2\int_{\mathcal{X}} fg d\Gamma(f,g)\Big| = \tfrac{1}{2}\int_{\mathcal{X}} f^2 d\Gamma(g,g) + 2\int_{\mathcal{X}} g^2 d\Gamma(f,f). \qquad (5.16)$$

Combining (5.15) and (5.16), and using the fact that $g \le c_1$, we obtain

$$\begin{aligned}\int_U f^2\, d\Gamma(g,g) &\le 4\int_U g^2 d\Gamma(f,f) + 2c_1\Psi(r)^{-1}\int_U g f^2 dm \\ &\le 4c_1^2 \int_U d\Gamma(f,f) + 2c_1^2 \Psi(r)^{-1}\int_U f^2 dm.\end{aligned}$$

Thus the hypotheses of Lemma 5.1 hold, and so CSA(Ψ) holds. □

Remark 5.6. While the proof above is based on the argument in Section 3 of [BBK], it is much simpler, since we do not need to consider the integral over arbitrary balls. Further, the condition CS(Ψ) requires Hölder continuity of the cutoff function, and this was proved by using a parabolic Harnack inequality, which is equivalent to the full (upper and lower) heat kernel bounds HK(Ψ). It seems unlikely that the conditions VD and UHK(Ψ) are sufficient to ensure the existence of a Hölder continuous cutoff function.

We conclude this section by giving a sketch of the proof that CSA(Ψ) follows from the condition CS(Ψ) introduced in [BB3, BBK].

Lemma 5.7. *Let $\mathcal{X}$ satisfy* VD. *Suppose that for every $x \in \mathcal{X}$ and $r > 0$ there exists a cutoff function φ for $B(x,r) \subset B(x,2r)$ such that if $f : B = B(x,2r) \to \mathbb{R}$ then, writing $V = B(x,2r) - B(x,r)$,*

$$\int_V f^2\, d\Gamma(\varphi,\varphi) \le c_1\Big(\int_V d\Gamma(f,f) + \Psi(r)^{-1}\int_V f^2 dm\Big). \qquad (5.17)$$

Then CSA(Ψ) *holds. In particular* CS(Ψ) *implies* CSA(Ψ).

Proof. Let $x_0 \in \mathcal{X}$, $R, r > 0$, and $B' = B(x_0, R)$ and $B = B(x_0, R+r)$, and $U = B - B'$. In view of Lemma 5.1 it is enough to prove that there exists $c_2 < \infty$ such that for $f : U \to \mathbb{R}$,

$$\int_U f^2 \, d\Gamma(\varphi, \varphi) \le c_2 \int_U d\Gamma(f, f) + c_2 \Psi(r)^{-1} \int_U f^2 dm. \tag{5.18}$$

Set $r_0 = r/3$, and let $B(z_i, r_0)$ be a covering of B' by balls such that $B'_i = B(z_i, r_0/2)$ are disjoint and each $z_i \in B'$. Then VD implies there exists M such that any ball $B(y, r_0/100) \subset B$ intersects at most M of the balls B_i. Let φ_i be a cutoff function for $B'_i \subset B_i = B(z_i, 2r_0)$ satisfying (5.17). Then

$$\int_{B_i} f^2 d\Gamma(\varphi_i, \varphi_i) \le c_1 \Big(\int_{B_i} d\Gamma(f, f) + \Psi(r_0/3)^{-1} \int_{B_i} f^2 dm \Big).$$

Now set $\varphi(x) = \max_i \varphi_i(x)$. Then φ is clearly 1 on B' and zero outside B.

If $B'' = B(y, r_0/100)$ and B_i, $i = 1, \dots m$ are the balls which intersect B'', then

$$d\Gamma(\varphi, \varphi) \le \sum_{j=1}^{m} d\Gamma(\varphi_j, \varphi_j).$$

Thus

$$\begin{aligned} \int_B f^2 d\Gamma(\varphi, \varphi) &\le \sum_i \int_{B_i} f^2 d\Gamma(\varphi_i, \varphi_i) \\ &\le \sum_i c_1 \Big(\int_{B_i} d\Gamma(f, f) + \Psi(r_0/3)^{-1} \int_{B_i} f^2 dm \Big) \\ &\le c_1 M \Big(\int_B d\Gamma(f, f) + \Psi(r_0/3)^{-1} \int_B f^2 dm \Big), \end{aligned}$$

proving (5.18). □

6 Stochastic Completeness

Proof of Theorem 1.16. Following Davies [D, Theorem 7] let $f \ge 0$ be a function with compact support and let $u_t = P_t f$. We remark that to prove stochastic completeness, by standard density arguments it is sufficient to prove that

$$\int_{\mathcal{X}} f \, dm \le \int_{\mathcal{X}} u_t \, dm \quad \text{ for some } t > 0. \tag{6.1}$$

Indeed, note that since P_t is self-adjoint in $L^2(\mathcal{X}, m)$, this implies $\langle 1 - P_t 1, f \rangle \le 0$ and therefore $P_t 1 = 1$ m-a.e.

Let (a_n) be an increasing sequence with $a_0 = 1$, and define φ, b_n, b^* and C_0 as in (2.2)–(2.4). We assume that (a_n) is chosen so that $b^* = 1$. Let $t \in (0, 1)$. Then

$$\langle f, \varphi_n \rangle - \langle u_t, \varphi_n \rangle = - \int_0^t \frac{d}{ds} \langle u_s, \varphi_n \rangle ds$$

and

$$-\frac{d}{ds}\langle u_s, \varphi_n\rangle = \mathcal{E}(u_s, \varphi_n) = \int_{\mathcal{X}} d\Gamma(u_s, \varphi_n).$$

So, by Cauchy-Schwarz and Proposition 2.2, and recalling that $t < 1$,

$$\begin{aligned}\langle f, \varphi_n\rangle - \langle u_t, \varphi_n\rangle &= \int_0^t \int_{\mathcal{X}} \varphi \cdot \varphi^{-1} d\Gamma(u_s, \varphi_n)\, ds \\ &\le \Big(\int_0^t \int_{\mathcal{X}} \varphi^2\, d\Gamma(u_s, u_s)\, ds\Big)^{1/2} \Big(\int_0^t \int_{\mathcal{X}} \varphi^{-2}\, d\Gamma(\varphi_n, \varphi_n)\, ds\Big)^{1/2} \\ &\le \sqrt{2}\, \|f\varphi\|_2 e^{2C_0 t} \big(\sup_{U_n} \varphi^{-1}\big) \Big(\int_{\mathcal{X}} d\Gamma(\varphi_n, \varphi_n)\Big)^{1/2}.\end{aligned}$$

On U_n we have $a_n \le \varphi \le a_{n+1}$, so $\sup_{U_n} \varphi^{-1} \le a_n^{-1}$. Using $\mathrm{CSD}(D_n, D_{n+1}, \theta_n)$ with $f = 1$,

$$\int_{\mathcal{X}} d\Gamma(\varphi_n, \varphi_n) = \int_{U_n} d\Gamma(\varphi_n, \varphi_n) \le \theta_n m(U_n).$$

So,

$$\langle f, \varphi_n\rangle - \langle u_t, \varphi_n\rangle \le \sqrt{2}\, \|f\varphi\|_2 \exp\Big(2C_0 t + \tfrac{1}{2}\log(\theta_n m(U_n)) - \log(a_n)\Big). \tag{6.2}$$

If there exists a subsequence (n_k) such that

$$\lim_{k\to\infty} (\langle f, \varphi_{n_k}\rangle - \langle u_t, \varphi_{n_k}\rangle) \le 0, \tag{6.3}$$

then, since

$$\int_{\mathcal{X}} u_t\, dm = \lim_k \int_{\mathcal{X}} u_t \varphi_{n_k}\, dm,$$

we obtain (6.1) and so deduce stochastic completeness.
(a) If $\theta_n \le c_1$ we choose $a_n = 2^n$, so that $b_n = b^* = 1$ and $C_0 = c_1 < \infty$. Then (1.20) implies that the right side of (6.2) converges to 0.
(b) (Recall in this case that $\theta_n = c_0^2 n^2$.) Let $\alpha > 0$, and consider sequences (a_k) such that $C_0 = C_0((a_k)) = \alpha^2$. We wish a_k to be as large as possible given these constraints, and so choose $b_k = 1 \wedge (\alpha/\theta_k^{1/2})$. Now fix $n \gg 1$, let $m = \lambda \log n$ where $\lambda > 0$, and let $\alpha = c_0 m$. We have

$$a_n = \prod_{j=1}^n \big(1 + b_j\big) \ge \prod_{j=m}^n \big(1 + \frac{m}{j}\big).$$

So since $\log(1+x) \ge \frac{1}{2}x$ for $x \in (0,1)$, for n large enough

$$\log a_n \ge \tfrac{1}{2} m \sum_{j=m}^n j^{-1} \ge \tfrac{1}{2}\lambda(\log n)(\log n - \log\log n - 1) \ge \tfrac{1}{3}\lambda(\log n)^2.$$

Writing $E(n, \lambda)$ for the term in the exponential in (6.2), if $\log m(U_n) \le 2b(\log n)^2$ then

$$\begin{aligned}E(n, \lambda) &= 2c_0^2 m^2 t + \tfrac{1}{2}\log(\theta_n m(U_n)) - \log a_n \\ &\le \tfrac{1}{2}\log(\theta_n m(U_n)) - (\log n)^2(\lambda\tfrac{1}{3} - 2c_0^2\lambda^2 t) \\ &\le \log c_0 n - (\log n)^2 \Big(\tfrac{\lambda}{3} - b - 2c_0^2\lambda^2 t\Big).\end{aligned}$$

Choosing $\lambda = 9b$ and t small enough so that $2c_0^2\lambda^2 t \le b$, it follows that

$$E(n,\lambda) \le -b(\log n)^2 + \log c_0^2 n,$$

and (6.3) holds. $\square$

Remark 6.1. We have just considered the cases $\theta_n \le c_1$ and $\theta_n = c_1 n$, as for our applications these are of most interest. By arguments similar to the above it is straightforward to show that if $\theta_n = c_0^2 n^{2\gamma}$ with $0 < \gamma < 1$, then stochastic completeness holds provided

$$\log m(U_n) \le c(\gamma) n^{1\wedge(2-2\gamma)}. \tag{6.4}$$

We now give some examples of the use of the criterion in Theorem 1.16, and begin by showing that we can recover the result of Davies [D].

Example 6.2. Let $\mathcal{X}$ be a manifold containing a point 0, and such that there exists $b > 0$ such that

$$m(B(0,r)) \le e^{br^2}. \tag{6.5}$$

Let (r_n) be increasing with $\lim r_n = \infty$. Set $D_n = B(0,r_n)$ and let $U_n = D_{n+1} - D_n$. Let φ_n be 'linear' on U_n, so that

$$\varphi_n(x) = 1 \wedge \Big(\frac{r_{n+1} - d(0,x)}{r_{n+1} - r_n} \vee 0\Big), \text{ and } ||\nabla\varphi_n||_\infty = \frac{1}{r_{n+1} - r_n}.$$

Letting $\theta_n = (r_{n+1} - r_n)^{-2}$, clearly we have

$$\int_{U_n} f^2 \, d\Gamma(\varphi_n,\varphi_n) \le \theta_n \int_{U_n} f^2 dm, \tag{6.6}$$

and so $\mathrm{CSD}(D_n, D_{n+1}, \theta_n)$ holds. Let $r_n = \log n$, so that $\theta_n \sim n^2$. Then $m(U_n) \le m(D_{n+1}) \le \exp(b(\log(n+1))^2)$, so (1.21) holds and $\mathcal{X}$ is stochastically complete.

Remark 6.3. Improving the condition $\log V(0,r) \le br^2$ to $\log V(0,r) \le r^2 \log r$ allowed by Theorem 1.15 seems to require more delicate techniques.

7 The pre-Sierpinski carpet

In this section we will give an example of an MMD space which is geodesically incomplete but stochastically complete. The example is based on the 'pre-Sierpinski carpet' – see [O1].

The standard Sierpinski carpet in d dimensions (with $d \ge 2$) can be constructed by an analogue of the construction of the Cantor set. Starting with $F_0 = [0,1]^d$, divide F_0 into 3^d subcubes each of side 3^{-1}, and remove the middle cube; call this set F_1. Repeating this construction, we obtain a decreasing sequence of compact sets F_n; the Sierpinski carpet is defined as

$$F = \cap_{n=0}^\infty F_n.$$

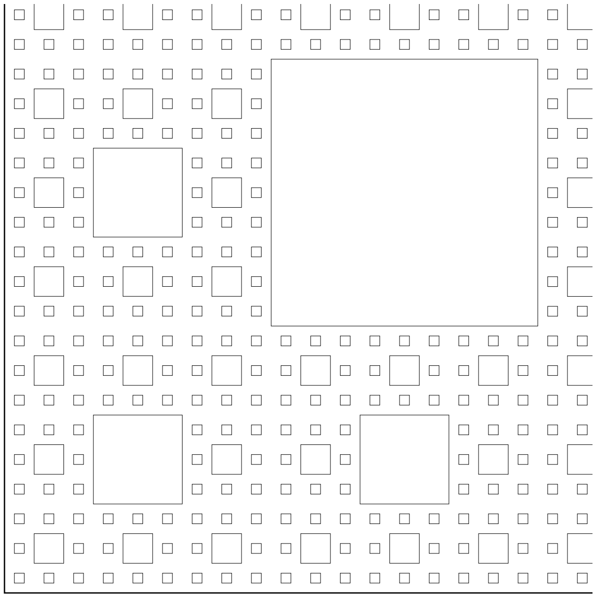

Figure 1: The pre Sierpinski carpet

Let $M_d = 3^d - 1$; then F has Hausdorff dimension

$$d_f = \frac{\log M_d}{\log 3}.$$

Note that F_n is a union of M_d^n cubes each of side 3^{-n}. Let

$$\widetilde{F}_n = 3^n F_n = \{3^n x : x \in F_n\}, \quad \widetilde{F} = \cup_{n=0}^{\infty} \widetilde{F}_n. \tag{7.1}$$

The set $\widetilde{F}$ is the *pre-Sierpinski carpet*, and is a countable union of copies of the unit cube $[0,1]^d$. The interior of $\widetilde{F}$ is a standard open domain in $\mathbb{R}^d$, with a Lipschitz boundary. We write $\mathcal{X} = \widetilde{F}$, and will take $d \geq 3$. Let μ be Lebesgue measure restricted to $\mathcal{X}$.

We summarise some properties of $\mathcal{X}$. Let $d(x,y)$ denote the shortest path distance in $\mathcal{X}$. Then (see [BB1, Lemma 7.3] for the case $d = 2$) we have

$$|x-y| \leq d(x,y) \leq c|x-y|, \quad x, y \in \mathcal{X}. \tag{7.2}$$

We write $B_d(x,r)$ for balls in the metric d. Then (see [BB2, Lemma 2.3(e)]) we have

$$V_d(x,r) = \mu(B_d(x,r)) \asymp \begin{cases} r^d, & 0 \leq r \leq 1, \\ r^{d_f}, & r > 1. \end{cases} \tag{7.3}$$

In particular $\mathcal{X}$ satisfies VD.

Now set

$$\mathcal{E}(f,f) = \int_{\mathcal{X}} |\nabla f|^2 \, d\mu, \qquad f \in H^1(\mathcal{X}),$$

where $H^1 = H^1(\mathcal{X})$ denotes the set of functions f for which $\int_{\mathcal{X}} f^2 \, dx + \mathcal{E}(f,f) < \infty$. Then $(\mathcal{E}, H^1)$ is a regular local Dirichlet form on $L^2(\mathcal{X}, \mu)$. The associated Hunt process $W = (W_t, t \geq 0, \mathbb{P}^x, x \in \mathcal{X})$ is Brownian motion in $\mathcal{X}$ with normal reflection on the boundary $\partial\mathcal{X}$. For the existence and uniqueness in law of this process we refer to [BH]. The process is reversible with respect to μ, and its generator is given by the Neumann Laplacian Δ on $\mathcal{X}$.

Let $p_t(x,y)$ denote the heat kernel associated with W. Many of the properties of W and p_t can be summarised by two indices. The first is d_f, the Hausdorff dimension of the space F. The second, denoted d_w, and called the *walk dimension*, gives the long range space-time scaling on $\mathcal{X}$. For Sierpinski carpets in $d \geq 3$ this satisfies $2 < d_w < d_f$ – see [BB2, Section 5]. Let $\Psi = \Psi_{2,d_w}$ be as defined in (1.3).

Theorem 7.1. *(a)* $(\mathcal{X}, \mathcal{E})$ *satisfies* HK(Ψ).
(b) W *has a Greens function* $g(x,y)$ *such that there exist positive constants* c_1*-*c_4 *such that*

$$\begin{aligned} c_1|x-y|^{2-d} \leq g(x,y) \leq c_2|x-y|^{2-d} \quad & \text{if } |x-y| \leq 1, \\ c_3|x-y|^{d_w-d_f} \leq g(x,y) \leq c_4|x-y|^{d_w-d_f} \quad & \text{if } |x-y| > 1. \end{aligned}$$

(c) The conditions CS(Ψ) *and* CSA(Ψ) *hold for* $(\mathcal{X}, \mathcal{E})$.

Proof. (a) is proved in [BB2, Theorem 6.9], and (b) in [BB2, Corollary 6.10]. That CS(Ψ) holds follows from [BBK]. CSA(Ψ) then follows by Lemma 5.7, or alternatively by Theorem 1.12. □

Let $a(x) > 0$, $x \in \mathcal{X}$ be a real-valued function on $\mathcal{X}$. Then, we define the additive functional

$$A_t = \int_0^t \frac{1}{a(W_s)} \, ds$$

and the time-changed process $Y = Y^{(a)}$ by

$$Y_t = W_{\tau_t}, \qquad t \geq 0,$$

where (τ_t) denotes the inverse of (A_t). The process Y is symmetric with reversible measure $m(dx) = m_a(dx) = a^{-1}(x)\,\mu(dx)$ and its generator $\mathcal{L}_a$ satisfies

$$\int g \mathcal{L}_a f a^{-1} \, d\mu = \langle \mathcal{L}_a f, g \rangle_{L^2(m_a)} = -\mathcal{E}(f,g) = -\int \nabla f \cdot \nabla g d\mu = \int (\Delta f) g d\mu,$$

so that

$$\mathcal{L}_a f = a \Delta f. \tag{7.4}$$

The Dirichlet form associated with Y is the form $(\mathcal{E}, \mathcal{D}_a)$ on the base space $L^2(\mathcal{X}, m_a)$. Here $\mathcal{D}_a$ is the closure of $C_0^1(\mathcal{X})$ with respect to $N_a(f) = \mathcal{E}(f,f) + ||f||^2_{L^2(m_a)}$. We refer to this form as $\mathcal{E}_a$ for short. Recall from (1.18) the definition of the intrinsic metric ϱ_a associated with $\mathcal{E}_a$; we have

$$\varrho_a(x,y) = \sup\{u(x) - u(y) : \, u \in \mathcal{M}_a, \}, \tag{7.5}$$

where

$$\mathcal{M}_a = \{u \in \mathcal{D}_a \cap C(\mathcal{X}) : \, |\nabla u|^2 \le a^{-1}\}. \tag{7.6}$$

Let $p > 0$. We now just consider the case

$$a(x) = 1 \vee d(0,x)^p. \tag{7.7}$$

The main result of this section is the following. Recall that we have $d \ge 3$, and that $2 < d_w < d_f$.

Theorem 7.2. *(i) The process $Y = Y^{(p)}$ is stochastically complete if and only if $p \le d_w$.*
(ii) On the other hand, (VGC) holds if and only if $p \le 2$ or $p > d_f$. In particular, for $p \in (2, d_w)$ the process Y is stochastically complete but (VGC) fails.

We begin by relating the metrics ϱ_a and d on $\mathcal{X}$.

Lemma 7.3. *Let $R > 0$, and $x \in \partial B_d(0,R)$, $y \in \partial B_d(0,2R)$. Then*

$$\varrho_a(x,y) \asymp R^{1-p/2}, \ \text{if } R \ge 1, \tag{7.8}$$

while $\varrho_a(x,y) \asymp R$ if $R \in [0,1]$.

Proof. By Theorem 4.1 in Chapter 5 of [St2] we have

$$\varrho_a(0,x) = \inf_\gamma \int_0^1 |\dot\gamma| \frac{1}{\sqrt{a(\gamma(s))}} \, ds. \tag{7.9}$$

If γ is any path in $B_d(0,2R) - B_d(0,R)$ then

$$\int_0^1 |\dot\gamma| \frac{1}{\sqrt{a(\gamma(s))}} \, ds \asymp R^{-p/2} \int \dot\gamma = R^{-p/2} |\gamma|,$$

where $|\gamma|$ denotes the length of γ. It follows that $\varrho_a(x,y) \ge cR^{1-p/2}$.

For the upper bound, the geometry of the pre-carpet implies that if $C > 1$ is large enough then we can find a path γ_1 between x and y which lies inside $B_d(0,CR) - B_d(0,R)$ and has length less than $c_1 R$. Therefore $\varrho_a(x,y) \le c_2 R^{1-p/2}$. □

Proposition 7.4. *The metric ϱ_a and measure m_a satisfy the following.*
(i) $\varrho_a(0,\infty) = \infty$ if and only if $p \le 2$. In particular, $(\mathcal{X}, \varrho_a)$ is not geodesically complete when $p > 2$.
(ii) $m_a(\mathcal{X}) = \infty$ if and only if $p \le d_f$.

Proof. (i) Let $x_k = (2^k, 0, \dots, 0)$ be the points on $\partial B_d(0, 2^k)$. Then by Lemma 7.3 we have $\varrho_a(x_k, x_{k+1}) \asymp 2^{k(1-p/2)}$. If $p \le 2$ the sum $\sum_k \varrho_a(x_k, x_{k+1})$ diverges, and hence $\varrho_a(0, x_k) \to \infty$, while if $p > 2$ then $\lim_k \varrho_a(0, x_k) \le C_1 < \infty$; (i) then follows.
(ii) By (7.3)

$$\begin{aligned} m_a(\mathcal{X}) &= \sum_k m_a(B_d(0, 2^{k+1}) - B_d(0, 2^k)) \\ &\asymp \sum_k 2^{-kp} \mu(B_d(0, 2^{k+1}) - B_d(0, 2^k)) \asymp \sum_k 2^{-kp} 2^{kd_f}, \end{aligned}$$

which is infinite if and only if $p \le d_f$. □

We now look at (VGC) for the metric measure space $(\mathcal{X}, \varrho_a, m_a)$. We set $h^{-1}(r) := \int_0^r (1 \vee s)^{-p/2}\, ds$, $r \ge 0$, so that $\varrho_a(0, x) \asymp h^{-1}(|x|)$ if $|x| \ge 1$. Further, let $h(r) := \inf\{s : h^{-1}(s) > r\}$ be the right-continuous inverse. In particular,

$$B_d(0, h(c_2 r)) \subseteq B_{\varrho_a}(0, r) \subseteq B_d(0, h(c_1 r)), \qquad r > 1.$$

Moreover, if $p \le 2$ we have $\lim_{r\to\infty} h^{-1}(r) = \infty$, so $h(r) < \infty$ for all r. On the other hand, if $p > 2$ we have that $R_0 := \lim_{r\to\infty} h^{-1}(r) < \infty$, thus $h(r) = \infty$ and $B_{\varrho_a}(0, r) = F$ for $r \ge R_0$.

Lemma 7.5. *Let $p \le 2 < d_f$. There exist positive constants c_1–c_5 and r_0 such that for all $r > r_0$*

$$c_1 h(c_2 r)^{d_f - p} \le m_a(B_{\varrho_a}(0, r)) \le c_3 h(c_4 r)^{c_5(d_f - p)}.$$

Proof. The lower bound is immediate from (7.3) as

$$\begin{aligned} m_a(B_{\varrho_a}(0, r)) &\ge \int_{B_d(0, h(cr))} \frac{1}{a(x)} \mu(dx) \\ &\ge \mu(B_d(0, 1)) + h(r)^{-p} \left(\mu(B_d(0, h(cr))) - \mu(B_d(0, 1)) \right) \\ &\ge c + c h(cr)^{d_f - p} \end{aligned}$$

for r sufficiently large, where we used the fact that h is increasing.

To prove the upper bound note that for $k \ge 0$ we have $a(x) \ge 2^{kp}$ on the set $U_k = B_d(0, 2^{k+1}) - B_d(0, 2^k)$. Let $k_0(r) = \min\{k : 2^k \ge h(cr)\}$. Then, for all r large enough we have again by (7.3)

$$\begin{aligned} m_a(B_{\varrho_a}(0, r)) &\le \int_{B_d(0, h(cr))} \frac{1}{a(x)} \mu(dx) \le \mu(B_d(0, 1)) + c \sum_{k=0}^{k_0(r)} m_a(U_k) \\ &\le c + c \sum_{k=0}^{k_0(r)} 2^{k(d_f - p)} \le c h(cr)^{c(d_f - p)}. \end{aligned}$$

□

Proof of Theorem 7.2

(i) First let $p \le d_w$. Let $R > 1$, $R_n = R^n$, $D_n := B_d(0, R_n)$ and $U_n = D_{n+1} - D_n$. Thus

$$m_a(U_n) \asymp R_n^{-p}\mu(U_n) \asymp R_n^{d_f - p}.$$

By Theorem 7.1 we have CSA(Ψ) for the space $(\mathcal{X}, d, \mathcal{E}, \mu)$. So there exists a cutoff function φ_n for $D_n \subset D_{n+1}$ such that if $f : U_n \to \mathbb{R}$ then

$$\begin{aligned}\int_{U_n} f^2 d\Gamma(\varphi_n, \varphi_n) &\le \frac{1}{8}\int_{U_n} \varphi_n^2 d\Gamma(f, f) + c_0 R_n^{-d_w}\int_{U_n} f^2 d\mu \\ &\le \frac{1}{8}\int_{U_n} \varphi_n^2 d\Gamma(f, f) + c_1 R_n^{p-d_w}\int_{U_n} f^2 dm_a.\end{aligned}$$

Thus in the space $(\mathcal{X}, \varrho_a, m_a)$, CSD$(D_n, D_{n+1}, \theta_n)$ holds with $\theta_n = c_1 R_n^{p-d_w}$. As $p \le d_w$ we have $\theta_n \le c_1$ and hence by Theorem 1.16(a) stochastic completeness holds provided (1.20) holds. However,

$$\frac{\theta_n m_a(U_n)}{4^n} \le c_1 4^{-n} R_n^{-d_w+p} R_n^{d_f-p} = c_1 (R^{d_f-d_w}/4)^n,$$

and taking R small enough so that $R^{d_f-d_w} < 4$ it follows that stochastic completeness holds.

Now we consider the case $p > d_w$. Since the process W is stochastically complete, from the definition of stochastic completeness it is immediate that Y is stochastically complete if and only if $A_\infty = \infty$ $\mathbb{P}^x$-a.s. for any x. Note that $A_\infty = \infty$ is a tail event, i.e. it is in $\sigma(W_s, s \ge t)$ for all t, so $\mathbb{P}^x[A_\infty = \infty]$ is either 0 or 1 for all x (cf. Theorem 8.7 in [BB2]).

Let $D_0 = B_d(0, 1)$ and for $n \ge 1$ set $D_n = B_d(0, 2^n) - B_d(0, 2^{n-1})$. Then using the bounds for the Green kernel $g(x, y)$ of W in Theorem 7.1(b),

$$\begin{aligned}\mathbb{E}^0 A_\infty &= \int_{\mathcal{X}} a(x)^{-1} g(0, x)\mu(dx) \\ &\le c\int_{B_d(0,1)} |x|^{2-d} dx + c\sum_{n=1}^{\infty}\int_{D_n} d(0, x)^{-p+d_w-d_f} dx \\ &\le c + c\sum_{n=1}^{\infty} 2^{n(-p+d_w-d_f)} 2^{nd_f} \le c + c\sum_{n=1}^{\infty} 2^{n(d_w-p)} < \infty,\end{aligned}$$

Hence, $A_\infty < \infty$ $\mathbb{P}^0$-a.s., and so Y is stochastically incomplete.

(ii) Let us first consider the case $p < 2$. Then, $d_f - p > 0$ and $h(r) \asymp r^\gamma$ for large r with $\gamma := (1 - p/2)^{-1}$. Hence, we use (7.3) to obtain

$$\int_1^\infty \frac{r}{\log m_a(B_{\varrho_a}(0, r))} dr \ge \int_1^\infty \frac{r}{c_1 + c_2 \log r} dr = \infty.$$

If $p = 2$, $h(r) = e^{r-1}$, so

$$\int_1^\infty \frac{r}{\log m_a(B_{\varrho_a}(0, r))} dr \ge \int_1^\infty \frac{r}{c_1 + c_2(r-1)} dr = \infty.$$

Finally, in the case $p > 2$ we have that $R_0 := \lim_{r\to\infty} h^{-1}(r) < \infty$, thus $h(r) = \infty$ and $B_{\varrho_a}(0,r) = \mathcal{X}$ for $r \geq R_0$. In particular, by Proposition 7.4 ii) we get for such r that $m_a(B_{\varrho_a}(0,r)) = m_a(\mathcal{X}) = \infty$ if and only $p \leq d_f$. Hence,

$$\int_1^\infty \frac{r}{\log m_a(B_{\varrho_a}(0,r))} dr \begin{cases} < \infty & \text{if } p \leq d_f, \\ = \infty & \text{if } p > d_f. \end{cases}$$
